LARGE 8vo. volume, bound in paper cover, price 24 M. (4l. 4s.). It contains Preface, Table of Contents, 560 pages of subject-matter, Alterations of the Patent Lists, a Register of the Numbers of the German Patents recorded, as also of the Applications for Patents, covering two pages, an Alphabetical Index of the holders of Patents, and finally, a complete Alphabetical Index, covering 13½ pages.

The classification of the matter of the contents is as follows: Intermediate products of the Tar Industry (1 to 15 pages). Triphenyl-, Diphenylmethane derivatives and Phthalene (pages 16 to 93). Indigo-blue, Isatine, and Indole Derivatives (pages 96 to 100). Quinolines, Quinazolines and Pyrazolone Derivatives (pages 102 to 127). Salicylic acid, Salicylic ether, and Phenolearboic acids (pages 130 to 140). Methylene Blue (pages 142 to 156). Oxazines, Phenazine-derivatives and Indophenol (pages 156 to 186). Indulines (pages 186 to 214). Nitro- and Nitroso compounds (pages 215 to 225). Naphthol- and Naphthylamine sulphonic acids, Dihydroxynaphthalenes, Amidohydroxynaphthalenes, and their Sulphonic acids and Naphthylenediamines (pages 229 to 278). Primuline dyes (pages 286 to 301). Azo-Dyes for Wool and Mordanted cotton (pages 308 to 337). Cotton Azo-dyes (pages 341 to 471). Dyes of various composition (pages 472 to 498). Compounds of various composition (Medicaments) (pages 501 to 558). The work gives a clear and precise account of all that has been done in Colour Chemistry, and in Synthetic aromatic Medicaments between the years 1887 and 1890.

CHEMISCH-TECHNISCHES REPERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der Technischen und industriellen Chemie. Mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von DR. EMIL JACOBS-EN, 1890, Erstes Halbjahr. Zweite Hälfte. Berlin: 1891, R. Gaertner's Verlagsbuchhandlung, Hermann Heyfelder, Schönebergerstrasse, 26. London: H. Grevel and Co., 33, King Street, Covent Garden.

The second issue for the first half year of 1890. It contains 203 pages of subject-matter, copiously illustrated with wood engravings. In the text the following branches of technology are treated of:—Food Stuffs; Paper; Photography, &c.; Waste Residues, Deposits, Manures, &c.; Disinfection and Sanitation; Soap; Explosives, Matches; Preparation and Purification of Chemicals; Chemical Analysis; Apparatus, Machinery, Electro-technology, Technology of Heat; Appendix, &c. The Annual Report concludes with Reviews of New Books.

The first issue for the second half year of 1890 has also appeared. It contains 96 pages of text illustrated with wood engravings. The following branches of technology are treated of:—Building Materials, Cements, and Artificial Stone; Colouring Matters, Dyeing and Calico Printing; Fats, Oils, Illuminating and Heating Materials; Fermented Liquors; Tanning, Leather, and Glue Manufacture; Textiles; Glass and Earthenware; Wood and Horn; India-rubber; Cements, Plasters, and Artificial Stone; Lakes, Varnishes, and Paints; Metals.

THE ROSE INDUSTRY OF BULGARIA. By CHRISTO CHRISTOFF, Kézanlik, Bulgaria. Translated by Chas. Henry Piesse. London: Piesse and Lubin, 2, New Bond Street.

OCTAVO, cloth bound pamphlet, with Preface, Table of Contents, and 60 pages of Text, illustrated by six Wood Engravings and a Map of the Otto of Roses producing region. Price 1s. The subject matter is divided into chapters headed as follows:—I. Historical; II. Geographical Situation; III. Botanical; IV. Plantations—Attention to Cultivation; V. Harvest—Distillation; VI. Otto of Roses; VII. Adulterations; VIII. Commerce.

PIESSE'S ART OF PERFUMERY, AND THE METHODS OF OBTAINING THE ODOURS OF PLANTS. The Growth and General Flower Farm System of Raising Fragrant Herbs, with Instructions for the Manufacture of Perfumes, &c., &c. Edited by CHAS. H. PIESSE, Consul-General of Monaco; Fellow of the Institute of Chemistry; Member of the Royal College of Surgeons, &c. Fifth Edition. London: Piesse and Lubin, 2, New Bond Street. 1891.

OCTAVO volume, with paper covers. The price is 10s. 6d. It has a frontispiece illustrating the Vender Still at Mitcham, Surrey; Preface to the Fifth Edition. In this preface the following noteworthy sentences occur:—"The excise duty on spirits of wine prevents England from fairly competing in her own colonies with her German and French neighbours in this particular trade." Also—"Female labour, so useful in this business, is prohibited by present regulations within 'bonded' warehouses. The workmen are also injured in the matter of their wages, as at present, 'no man is allowed to work after four o'clock.'" "These things, fairly considered, are a hard 'set off' against the English manufacturing perfumers compared with the facilities given by the French Government to the same trade." The author refers to the increasing favour shown to English perfumery, and adds, "for England now produces the finest perfumery in the world."

Next follows the Table of Contents, List of Illustrations (some 71 in number), 474 pages of subject matter, and an Appendix of eight pages. The work terminates with an Alphabetical Index. The text is subdivided into chapters treated as follows:—I. Introduction and History;

II. Theory of Odours; III. Flower Farming Statistics; IV. Expression, Distillation, Absorption, Enfleurage, Maceration; V. Primitive Odours, The Commercial Elements; VI. Perfumes of Animal Origin; VII. Smelling Salts, Snuff, and Vinegars; VIII. Bouquets and Nougays; IX. Sachet-powders and Incense; X. Perfumed Soap; XI. Emulsines; XII. Milks, or Emulsions; XIII. Cold cream; XIV. Pomades and Oils; XV. Hair Dyes and Depilatory; XVI. Absorbent Powders and Rouge; XVII. Tooth-powders and Mouth-washes; XVIII. Hair-washes; XIX. Of the Colours used by Perfumers; XX. Foreign Tariffs on Perfumery.

A THEORETICAL AND PRACTICAL TREATISE ON THE MANUFACTURE OF SULPHURIC ACID AND ALKALI WITH THE COLLATERAL BRANCHES. By GEORGE LUNGE, Ph.D., Professor of Technical Chemistry at the Federal Polytechnic School, Zürich. (Formerly Manager of the Tyne Alkali Works, South Shields.) Second Edition, Revised and Enlarged. Volume I.—Sulphuric Acid. London: Gurney and Jackson, 1, Paternoster Row. 1891.

THE work opens with a preface to Volume I. of the First Edition, another to Volume III. of the First Edition, and a very important and interesting one it is, and finally the Preface to the Second Edition. The Table of Contents follows, then the Introduction, and finally the text, covering 903 pages. The work concludes with a carefully arranged Alphabetical Index. The illustrations and drawings number no less than 374, and are beautifully executed. The price of the work (Vol. I.) is 2*l.* 2*s.*

CHAPTER I. is devoted to Historical and General Notes on the Manufacture of Sulphuric Acid. II. The Raw Materials of the Sulphuric Acid Manufacture; Brimstone; Pyrites; other Metallic Sulphides; By-products of other Manufactures; Nitrate of Soda and Nitric Acid. III. The Properties and Analysis of the Technically employed Oxides and Acids of Sulphur. IV. The Production of Sulphurous Acid. V. The Burner Gas. VI. Construction of the Lead Chambers. VII. The Chamber Process. VIII. The Recovery of the Nitrogen Compounds. IX. Theory of the Formation of Sulphuric Acid in the Lead Chambers. X. The Purification of Sulphuric Acid. XI. The Concentration of Sulphuric Acid. XII. Arrangement of the Apparatus of Sulphuric Acid Works. XIII. Yields and Costs of Sulphuric Acid Manufacture. XIV. By-Products of the Manufacture of Sulphuric Acid. XV. The Manufacture of Nordhausen or Fuming Oil of Vitriol, and of Sulphuric Anhydride. XVI. Other Processes of Manufacturing Sulphuric Acid. XVII. Applications of Sulphuric Acid, and Statistics. Appendix.

In view of the large amount of new work in the way of invention and improvement that has been done within the last few years, and the necessary description of more or less of it, the author has curtailed the merely retrospective portion, which describes processes and apparatus not now in use. However, though much of the latter has been cut down in this the Second Edition, the author refers in such places to the First Edition where the fuller descriptions may yet be found. The same observation applies to specific gravity tables and similar matter. Thus the First Edition remains useful, and should not be dispensed with. Much space is saved also by eliminating discussions or refutations of views now entirely obsolete. The author remarks that "hardly a single page now stands as it did in the first edition," and he very straightforwardly, if not bluntly, acknowledges that in sundry places he has not scrupled to contradict some few statements in the First Edition he then took to be fact, which by dint of closer observation and wider experience, he now regards more or less as error.

LE TITRAGE DES SOLUTIONS SACRÉES, PAR LA DÉTERMINATION DE LEURS DENSITÉS, À LA TEMPÉRATURE DE 15 CENTIGRADE. Par C. SCHIEBLER. Traduit de l'Allemand par D. Sidersky. Berlin: R. Friedlaender and Fils.

The German title of the original Work is "DIE GEBHALTS-ERMITTLUNG DER ZUCKERLÖSUNGEN DURCH BESTIMMUNG DES SPEZIFISCHEN GEWICHTS DERSELBEN BEI DER TEMPERATUR VON 15 CÉLSEUS."

Octavo, paper cover, 188 pages, price 8s. The work consists of two carefully compiled and important tables, Table I. being for aqueous solutions of sugar ranging from 0 to 100 per cent., with values increasing for every variation of 0.01 per cent., giving the densities and the corresponding strength in sugar for 100 parts by weight, and also for 100 parts by volume, at the temperature of 15° C.

Table II. is for converting to the normal temperature of 15° C., sugar solutions, the strength of which has been observed at any temperature from 0 to 50° C.

In the preface it is stated that "the determination of the strength of saccharine solutions by means of their densities implies that the operation is conducted at a fixed temperature which is the same for all the experiments; that is to say, a *normal temperature* at which all the necessary instruments are graduated, and for which the tables are calculated. Up to a short time ago, the *normal temperature* in Germany was 11° R. or 17° C. But quite recently, the Imperial Commission of Weights and Measures, sitting at Berlin, having been solicited to establish the official verification of hydrometers, has decided to take 15° C. as the normal temperature for that purpose, because that temperature is the basis for taking the strength of alcohol and is also frequently employed in scientific researches," &c. The task of constructing the new tables has been carried out by Professor Schiebler in an able and painstaking manner, and these tables cannot fail to prove of great service to those who are engaged in the sugar industry.

WATLES AND WATTLE-BARKS: being Hints on the Conservation and Cultivation of Wattles together with Particulars of their Values. By J. H. MAIDEN, F.L.S., F.C.S., &c. Second Edition. Sydney: George Stephen Chapman, Acting Government Printer. 1891.

Octavo volume in paper cover, price 1s., No. 6 of the Technical Education Series. It contains an Introduction to the First Edition; also a testimony from the Director General of Forests (Sydney) to the effect that he has much pleasure in recommending the work as an excellent Treatise upon the subject of Wattle Cultivation generally. In the immediately succeeding Preface to the Second Edition, the object of the pamphlet is set forth as for the purpose of supplying "farmers, tanners, merchants, and others, with authentic information in regard to the value of wattles." Australia is stated as being the native country of wattles, which will grow in the poorest soil, some requiring only a moderate rainfall. Their cultivation is strongly recommended to farmers who have a patch of poor soil which they cannot otherwise profitably utilise. The return is in about five to seven years. At present only the following wattles are recommended to be planted.—The South Australian Broad leaf Wattle, *Acacia pyramanthar*, and the various varieties of *Acacia dealbens*, generally known as Black or Green Wattle.

There follow next a Table of Contents, List of Illustrations, numbering 10, and text covering 74 pages. The work concludes with an Alphabetical Index.

Trade Report.

(From the Board of Trade Journal.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

Russia.

The Effect of Import Duties.

In the course of a report on the Russian import duties, Mr. J. Michell, Her Majesty's Consul at St. Petersburg, has the following:—

In order to stimulate the exportation of mineral and other resources of the country, the importation of some articles of this class, hitherto free, will now be made subject to payment of duty. Under this head are ranged sulphur, clay, and stones for building purposes, bones, raw and worked phosphorites, superphosphates, and composts. At the same time it is satisfactory to note that the duty on coal will remain for a certain period unchanged. On machinery the duty has been considerably raised, with the exception of that on agricultural machines and implements, which has been reduced to its previous level of 70 c. gold per pound.

On chemicals the duty has been considerably increased; thus caustic soda, hitherto 72 c. gold per pound, will now pay 90 c. gold; bleaching powder from 52 c. is now dutiable at 70 c. gold; borax from 11 c. gold has been raised to 120 c. per pound. Business in these particular goods is said to be now at a standstill, the consumer not being able to pay the increased price. The rates under this head are in fact prohibitive, as they are intended to be, with a view to benefiting the native manufacturers of chemical products.

The native iron trade was so encouraged that no further protection was necessary. Iron wire is sold at the cost of the duty; the duty on iron joists, formerly 60 c. gold per pound, has now been made 85 c., or 100 per cent. *ad valorem*. Pig-iron, with a duty of 30 c. gold per pound, which is the same as heretofore, is equal in price at the present rate of exchange of 9 r. 25 c. to 1*l.* to 3*l.* per ton, while the Middlesbrough price is only 40s. per ton f.o.b. The low price of the rouble which prevails at present makes importation of pig iron therefore almost impossible.

UNITED STATES.

Customs Decisions.

The following decisions respecting the construction to be given to Acts of Congress relating to the classification of articles in the Customs tariff, and the application of the Customs laws of the United States, have recently been given by the Customs authorities in that country:—

Nitrite of soda is classified as a "chemical salt," and is dutiable at 25 per cent. *ad valorem*, under paragraph 92 of the Tariff Act of March 1883, which levies this rate of duty on "all chemical compounds and salts, by whatever name known, not specially enumerated or provided for."

Degras or brown wool grease is dutiable at one half of one cent. per pound.

Atropine sulphate is dutiable, under paragraph 74, at 50 cents a pound.

Spermaceti is dutiable at 8 cents a gallon, under the provisions of paragraph 46 N.T., for whale oil.

Naphthionate of soda, a compound formed by the treatment of naphthalene, a constituent of coal-tar, with sulphuric acid, potassium cyanide, and sodium hydroxide is dutiable only at 20 per cent., under paragraph 19 as a coal-tar preparation.

NEW ROUMANIAN CUSTOMS TARIFF.

The following is a statement showing the rates of import duty now leviable in Roumania on certain articles of British produce or manufacture:—

Note.—Lei = 1 franc. Bani = 1 centime.

PAPERS OF INTEREST TO TECHNOLOGISTS AND MANUFACTURERS.

The following articles in the *Board of Trade Journal* for October will repay perusal:—

"The Petroleum Trade of Russia," p. 383.

"The Development of Mexico," p. 385.

"The Resources of Assam," p. 388.

"The Resources of Bolivia," p. 433.

GENERAL TRADE NOTES.

AUSTRIAN MINERAL PRODUCTION, 1890.

The figures relating to the production of the mines of Austria (proper), recently published by the Austrian Ministry of Agriculture in their "*Jahrbuch*" for 1890, are given in the *Handels Museum* of 10th September, from which we find that the total value of the mine products for 1890 was 68,167,000 florins (6,816,700*l.*), and of smelting products 36,889,000 *fl.* (3,688,900*l.*). The number of persons employed in mines and smelting houses was 121,678, and the average value of mine and smelting products produced by each employé was 745 *fl.* (74*l.* 10*s.* 0*d.*). The total value of Austria's mining and smelting produce, after deducting the value of the ores sent to the smelting houses, was 90,716,000 *fl.* (9,071,600*l.*). The values of the various mining products were as follows:—Coals, 30,401,078 florins (3,040,108*l.*); peat, 27,639,115 *fl.* (2,763,911*l.*); silver ore, 3,167,179 *fl.* (316,718*l.*); iron

ore, 3,415,765 lb. (310,576 lb.); lead ore, 969,622 lb. (96,962 lb.); quicksilver ore, 891,687 lb. (89,169 lb.); graphite, 726,036 lb. (72,604 lb.); zinc ore, 568,812 lb. (56,881 lb.); copper ore, 343,422 lb. (34,342 lb.); sulphur ore, alum, and vitriol shale, 100,261 lb. (10,026 lb.); and other ores, 251,166 lb. (25,117 lb.).

The values of the smelting products were as follows:—Pig iron, 27,310,617 lb. (2,731,062 lb.); silver, 3,257,927 lb. (325,792 lb.); lead and litharge, 1,696,019 lb. (196,605 lb.); quicksilver, 1,596,563 lb. (159,656 lb.); zinc, 1,467,892 lb. (146,789 lb.); copper, 602,163 lb. (60,216 lb.); sulphuric acid, 441,947 lb. (44,195 lb.); coppras and alum, 140,616 lb. (14,062 lb.); other metals and smelting products, 371,836 lb. (37,184 lb.).

In addition there are the products of the salt industry, the total estimated monopoly price of which was 23,040,106 lb. (2,304,011 lb.), showing an increase on the previous year to the extent of 1,461,551 lb. (14,616 lb.).

Compared with the year 1889 there is an increase of 9·2 millions of florins, or 15·65 per cent., in the total value of the mining products, the figures of 1890 and 1889 being, roughly, 68·16 millions and 58·96 millions of florins respectively. Comparing the total values of the smelting products for 1890 and 1889 the figures are, roughly, 36·89 and 32·75 millions of florins respectively, showing an increase in 1890 of 1·14 millions of florins, or 12·64 per cent.

The value of the mining and smelting products together was, as already stated, in 1890, 30·7 millions of florins, which, compared with the preceding year, shows an increase of 11·9 millions of florins, or 15·11 per cent.

Note. The florin has been taken at the nominal value of 2s.

DISCOVERY OF ANTHRACITE IN CANADA.

The discovery of new deposits of anthracite coal in the province of Alberta, comprising a portion of what was formerly known as the North West Territory of the Dominion of Canada, will prove, if the reports are correct, highly important not only to Manitoba and British Columbia but also to the Pacific Coast States of this country, there being no import duty on anthracite coal. It is said that large seams of this coal have been found along the Red Deer River, 10 miles north of Banff. Hitherto, it has been supposed that the only anthracite coal in Canada was at Anthracite, near Banff, from which place the present supply for the western part of the Dominion is taken.—*Engineering and Mining Journal*.

RECENT TESTS OF NICKEL STEEL ARMOUR PLATES.

Experiments made on the 12th inst. at the Annapolis proving ground have again confirmed the superiority of nickel steel over ordinary steel for armour plates. The tests were made to determine the value of nickel steel for a protective deck. The targets were made of two superposed 4-in. plates, placed almost horizontally, presenting an angle of only 2° to the line of fire. A 6-in. rifle was used, with a 100 lb. armour piercing projectile. When fired at the target of ordinary steel the target was perforated, and the projectile, which was broken, passed through both plates and through 2 ft. of wood and 8 ft. of earth composing the backing. The velocity of the projectile was 1,780 ft. per second. When fired at the nickel steel target, the velocity of projectile was 1,873 ft., but it glanced off the target without rupturing either plate, but was itself smashed to pieces. Its effect on the target was a small crack 5 in. long in one plate and an indentation between 3 in. and 5 in. deep.

The demonstration of the superiority of nickel steel over ordinary steel for armour plate suggests that it may have other valuable uses in the arts. A wish held for metallurgical research is here afforded. In this connection it seems strange that the world has waited so long for the discovery of the qualities of nickel steel to be made. For more than 20 years the open hearth steel process has been in successful use, producing the poorest known varieties of carbon steel, and during all this time it would have been an easy matter to make experiments on alloying this steel with other elements, and to determine the physical qualities of these alloys, yet it has been only within a year or so that such experiments have been seriously attempted. During

these 20 years millions of money have been spent in Europe in the manufacture of compound armour plate, viz., wrought iron with a steel face, all of which has now to be abandoned in view of the superiority of nickel steel, while the much simpler method of making a steel plate with a simple alloy has remained undiscovered. The time is ripe for further researches into the qualities of other alloys of steel. There are unlimited possibilities of the discovery of valuable qualities in numerous alloys yet untried; and it should be a matter neither of great difficulty nor of great expense for any open-hearth steel works to make the experiments which may result in such discoveries.—*Ibid.*

GUTTA-PERCHA.

The price of gutta-percha has nearly doubled in two years, and now rules at 5s. 3d. per lb. This remarkable advance in the price of the article is attributed to two causes, the large quantities required in the manufacture of electric and other modern devices and the reckless destruction of the trees from which the gum is obtained. This gum or sap is not obtained by merely tapping the trees, as is done by the gatherers of crude rubber along the River Amazon and its tributaries; the Malays and natives of Borneo, who collect gutta-percha, fell each tree from which gum is to be extracted, and thus the destruction of the trees and the consequent scarcity of the product is explained. From 1854 to 1875, 90,000 piculs, weighing 133½ lb. each, of gutta-percha were exported from Sarawak alone, and this meant the death of 3,000,000 trees. As no trees are planted, the reason that this species of plant has been saved from annihilation is that it does not produce the gum in paying quantities until it is 25 to 30 years old.—*Iron*.

THE PRODUCTION OF CRUDE GLYCERIN.

The basis for the preparation of the chemically pure glycerins used in pharmacy is the so-called saponification crude glycerin of the stearin works. The total output of crude glycerin in the world is said to be 40,000 tons per annum, of which 11,000 tons are obtained in soap manufacture, and 29,000 tons in stearin manufacture. Of the glycerin gained in soap-making, 5,500 tons are produced in the United Kingdom, 3,500 tons in France, 3,000 tons in the United States, and 2,000 tons in Germany. Many more countries participate in the production of stearin-glycerin, their approximate shares being as follows:—France, 6,000 tons; Germany, 3,000 tons; United States, 3,000 tons; Holland, 2,000 tons; Austria, 2,000 tons; Russia, 2,000 tons; Belgium, 1,800 tons; Italy, 1,800 tons; Spain, 1,500 tons; United Kingdom, 1,200 tons; Sweden and Norway, 350 tons; Switzerland, 300 tons; the Argentine, 300 tons; Australia, 300 tons; Portugal, 200 tons; Roumania, 150 tons; and Greece, 100 tons. Paris is the centre of the crude glycerin trade, and the place whence most of the speculative movements in the article originate. Between 1861 and 1891 the Paris quotation for crude standard glycerin has varied from 35 to 265 frs. per 100 kilos. In 1881 the price was forced up to 205 frs., but at that point the consumption suddenly decreased, while the stearin and soap works, enticed by the enormous price of the article, increased their output to an abnormal degree. Then the crash came, and in the summer of 1882 the quotation came down to 120 frs. Quite recently a process is said to have been discovered by which soapmakers are enabled to recover the entire proportion (10 to 12 per cent.) of glycerin in the fat in an almost pure condition, and with very simple and cheap apparatus. This process will very materially affect the glycerin industry, as the glycerin from the soap ley has hitherto been used almost exclusively for dynamite making. The output of this explosive in 1886 was estimated at 10,000 tons.—*Chemist and Druggist*.

THE GERMAN CHEMICAL INDUSTRY.

In the official report read at the annual general meeting of the Association for the Protection of the Interests of the (German) Chemical Industry, held at Nuremberg last month, the secretary stated that during the year 1890 there

had been a great advance in this important branch of German industry. The number of fully employed workmen employed had risen from 90,585 to 97,498; the total of wages paid from 71,611,000 marks to 80,075,000 marks. The average dividend paid by 82 limited companies, with an aggregate capital of 198,073,000 marks, rose from 10·58 in 1889 to 12·81 per cent. in 1890. These favourable results are not due to higher prices, but to increased sales of the products in various directions. An active participation at the forthcoming Chicago Exhibition was strenuously urged upon the members. A committee was appointed at the meeting to investigate the question of Sunday labour and draw up a report on the subject for presentation to Parliament.—*Ibid.*

MANCHESTER CHAMBER OF COMMERCE.

Report of the Chemical Section.

To the President and Directors of the Manchester Chamber of Commerce: Gentlemen, the Chemical Section of your Chamber having been requested to report upon a memorial presented by certain chemical and other manufacturers of this city with reference to smoke abatement, beg to state that they are of opinion:—1. That the emission of black smoke may generally be restricted, but that there are certain manufacturing operations in which its prevention is not practicable with our present means and appliances, and this is especially the case in carrying out processes in which the firing is of an intermittent character, or where very high and constantly varying temperatures require to be quickly obtained, or where some of the constituents of the coal enter into chemical combination with the article to be produced. We refer, amongst others, to metallurgical operations, the manufacture of glass, pottery, earthenware, soda ash by the Leblanc process, and to destructive distillation and distillation in retort glasses and stills. 2. That there exist no technical difficulties in reducing the smoke from ordinary boiler fires to a minimum. 3. That the use of anthracite or smokeless coal is not practicable in carrying out manufacturing operations in which the cost of fuel is an important item. Furthermore, anthracite is not suitable for many operations in which bituminous coal is absolutely necessary. In many chemical and metallurgical works a reducing flame is often necessary to carry out certain operations; in other words, air must not be admitted in sufficient quantity to completely burn the carbonaceous products, as if excess of air were introduced the product would be spoiled. In all such operations the production of black smoke cannot be prevented in the present state of our knowledge. 4. That the emission of black smoke may, however, be reduced with greater success even in some of the special processes referred to if manufacturers were able to secure cheaper coal-gas and coke at reasonable prices, as either of these, or in some instances the combination of both, might be found in certain cases to answer for a substitute of coal, as, for example, in retort firing, destructive distillation, and other operations. 5. Your committee's attention having also been called to a letter of the Manchester and Salford Noxious Vapours Association addressed to the Chamber, they have to say that the Association must have entirely misconceived the complaints made by the memorialists with reference to certain prosecutions for the emission of black smoke. The letter of the Association admits the exemption by the Legislature of certain manufactures, whilst as a matter of fact, prosecutions had been commenced against manufacturers carrying on the works and trades thus exempted. 6. That chemical works have not been specially mentioned as exempted by the Act is true, nor was there any need for it, as they are included in the general protecting clause (as already set forth in the memorial), which provides that any complaints should be dismissed if the court is satisfied that the furnace or fireplace is constructed in such a manner as to consume as far as practicable, having regard to the nature of the manufacture or trade, all smoke arising therefrom, and if such furnace or fireplace has been carefully attended to by the person having charge thereof (section 91, Public Health Act, 1875). In regard to the statement of the chief inspector referred to in the letter, the inspector may be theoretically right, that the prevention of the emission of

black smoke is not impossible in certain cases where smokeless coal might be used, but in practice the high price of this coal, which is almost four times as high as that of ordinary coal, and for reasons already stated excludes its substitution for the latter in almost all the manufacturing operations referred to. Moreover, the chief inspector, whose authority and experience principally attend to alkalis and noxious vapours, confined his remarks, we venture at least to think, solely to these, but there exists a number of chemical operations in which the conditions and circumstances are very much different. Finally the committee observes that the Association is wrong in assuming that the Chemical Sectional Committee is practically identical with the memorialists. The fact is that the majority of signatures to the memorial are in no wise those of firms connected with chemical works, and only few of them are represented on the Chemical Sectional Committee.—I have the honour to be, gentlemen, yours obediently, IVAN LEVINSTEIN, Chairman. —*Chemical Trade Journal.*

RECENT TRADE BLUE BOOK.

Thirty-fourth Report of the Commissioners of Her Majesty's Inland Revenue for the year ended 31st March 1891, with Appendix. (C.—6537.) Price 6d.

The following table shows net receipts of Excise in the years ended 31st March 1891 and 1890:—

	Year ended 31st March.		Increase.	Decrease.
	1891.	1890.		
	£	£	£	£
Spirits.....	14,770,730	13,860,002	910,728	..
Beer.....	9,390,111	9,110,126	..	20,285
Tobacco, home grown	131	86	45	..
Licences.....	230,150	530,215	..	299,795
Chicory.....	1,587	1,509	78	..
Coffee mixture labels	2,569	2,453	127	..
Railways.....	324,118	324,161	..	343
Charges on deliveries from bonded warehouses, &c.....	4,200	4,070	130	..
	21,723,917	21,133,232	911,108	320,423
			Net increase £500,685	

Under the head of "Spirit Duty," there is a large increase of 910,728*l.*, being at the rate of 6·7 per cent. over prior year.

The increase chiefly occurred in June and September quarters, 1890, and was incidental to the general improvement in trade. The further sum of 703,557*l.* was also raised under spirit duty at 6*d.* additional per gallon, under the 7th section of Act 53 Viet. c. 8, which took effect from 18th April 1890. This amount was paid over direct to Local Taxation Account.

The number of distilleries at work during the year ended 30th September 1890 was, in England, 10; in Scotland, 124; and in Ireland, 29; being a decrease of 2 in Scotland, and an increase of 1 in Ireland as compared with the previous year. The following is an estimate of the quantities of the principal materials used:—Malt, 946,398 quarters; unmalted grain, 1,140,380 quarters; molasses, 175,873 cwt.; rice, 41,993 cwt.; sugar, 453 cwt.; saccharum, 37,941 cwt. It is stated that the average consumption per head in the United Kingdom, which from 1881 to 1889 had declined in each year, had risen in the year ended 31st March 1891 to 0·775. The previous year it was 0·736 gallon.—*Board of Trade Journal.*

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

15,734. A. Henze-Frison. Improvements in gas and air valves for glass works, ice works, and for other uses. September 16.

15,740. G. Stonehouse and H. Simon. An improvement in centrifugal drying machines. Complete Specification. September 16.

15,785. O. Imray.—From C. Spaeter, Germany. Improvements in regenerative and other gas furnaces. September 17.

15,815. P. Pileiderer.—From Werner and Pileiderer, Germany. Improvements in universal mixing, kneading, pugging, crushing, breaking, grinding, levigating, triturating, malaxating, masticating, and amalgamating machinery. September 17.

16,011. O. March. A novel improved apparatus for the automatic and continuous extraction of liquid from semi-fluid substances. September 21.

16,218. T. Ledward. Improvements in or relating to open air fluid condensers. Complete Specification. September 24.

16,281. B. L. Fletcher and J. Hoyle. See Class XV.

16,560. J. P. Lancaster. Improvements in rail chairs. Complete Specification. September 29.

16,666. R. H. Yeomans. Improved method of heating and evaporating brine and other liquids. October 1.

16,806. J. Ellis. Improvements in ozonising apparatus. October 3.

16,904. A. Suiter and A. R. Margary. Improvements in regulators for compressed gas. October 5.

16,965. R. Morris. Improvements for preventing incrustation in steam boilers. October 6.

16,999. C. M. Martin and A. E. Tavernier. An improved thermostat. October 6.

17,031. H. C. Cox. Improvements in apparatus for the automatic control of sulphuric acid supply to carbonic acid generators used in aerated water manufacture and other industries. Complete Specification. October 7.

17,185. T. Scott. See Class VII.

17,274. R. W. Deacon.—From W. Maxwell, Java. See Class XVI.

17,401. J. Miles. The production of anti-corrosive boiler fluid from a vegetable compound. October 13.

17,623. W. H. Bowers. Improvements in retorts for the carbonisation of wood and other vegetable substances, and the drying of manures, sewage, sludge, peat, and other substances and products. Complete Specification. October 15.

17,750. J. J. McDaniel. Improvements in the method of and apparatus for securing a continuous time record of the rate of distillation and direction of flow of distilled fluids. October 16.

COMPLETE SPECIFICATIONS ACCEPTED.*

1890.

16,326. T. Shafter. Multiple evaporating apparatus. October 14.

18,050. T. Thorp. New apparatus for clarifying liquids. October 14.

19,199. J. Kent. Thermometers. September 30.

19,981. H. Cotton. Construction of mills for grinding flint stone, bone, glaze, and other like substances. October 14.

20,309. F. C. C. Baly. Mercury vacuum pumps. September 30.

1891.

10,738. C. H. Haubold. Centrifugal machine for incorporating or mixing together various substances. October 14.

11,413. B. D. Hedey. Cauldrons for melting pitch and fatty substances. September 23.

12,512. E. Donard and G. Boulet, jun. Apparatus for desiccation of solid matters. September 23.

13,612. R. Crow. See Class XVII.

15,092. O. Lindemann. Steam and vacuum pumps for raising liquids. October 14.

15,740. G. Stonehouse and H. Simon. An improvement in centrifugal drying machines. October 21.

H.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

15,535. H. Brier and V. Jackson. Improvements in or connected with apparatus or means for obtaining oxygen and nitrogen from the air. September 14.

15,552. R. Orr and R. M. Sutherland. See Class III.

15,905. A. E. Dean. The purification of gases and vapours from accompanying fluids. September 19.

15,975. H. Brier. Improvements in or connected with apparatus or means for obtaining oxygen and nitrogen from the air. September 21.

16,013. S. Lewis. Solidifying and reliquefying petroleum and mineral or other volatile oils. September 21.

16,021. J. Ruscoe. Improvements in apparatus for charging inclined gas retorts. September 21.

16,578. H. W. P. Nugent. Improvements in retort-charging apparatus. September 30.

16,907. L. T. Wilcox. Improvements in devices for heating and lighting. Complete Specification. October 5.

16,915. R. F. Strong. An improved smokeless block fuel and manufacture thereof. October 5.

17,222. W. Creswick. Improved arrangement of coke ovens and retorts for the manufacture of coke and illuminating gas. Complete Specification. October 9.

17,298. Brin's Oxygen Co., Lim., and K. S. Murray. See Class VII.

17,302. F. J. Jones. An improvement in the manufacture of coke. October 10.

17,351. G. R. Prowse. Improvements in apparatus for forming oxy-calcium lights. Complete Specification. October 12.

17,368. G. B. Mee.—From E. Fahrig, United States. An improvement in the production of oxygen. October 12.

17,371. K. Lares. An improved coke furnace or oven. Complete Specification. October 12.

17,422. J. Swallow, C. West, T. Needham, H. Milling, J. A. Compston, H. Owen, D. J. Bailey, and A. Haughton. Improvements in or relating to the treatment of paraffin and other oils for rendering it or them odourless, smokeless, miscible, and non-explosive. October 13.

17,447. T. Settle. Improvements in gas and other retorts, and in the method of setting and resetting them. October 13.

17,510. E. L. Pease. An improved apparatus to be used for the purification of gas or for analogous or similar purposes. October 14.

17,557. A. Kitson. Improvements in apparatus for manufacturing gas. Complete Specification. October 14.

17,587. W. C. Hoskins and J. Crighton. Improved appliances for increasing the illuminating power of gas and other light and for neutralising the noxious effects of the vapours emitted in the combustion of gas or other luminants. October 15.

17,613. J. Lyle. Novel means for the transformation of oil into a gas and the utilisation of such gas as the agent for heating purposes generally. October 15.

17,652. H. H. Lake.—From the Thomson-Houston International Electric Company, United States. Improvements in carbons for electric arc lamps. Complete Specification. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,998. J. C. Lawson. Manufacture of oxygen. October 14.

17,261. L. Van Vestrant. Setting inclined carbonising or gas retorts. September 23.

18,230. L. Van Vestrant and M. Graham. Construction of shoots for charging inclined gas retorts. October 7.

* See Note (c) on previous page.

18,360. H. Guyon and L. Métais. Manufacture of combustible gas for heating, lighting, and generation of motive power. October 21.

18,457. M. M. Brophy. Utilisation of gas for heating purposes, and apparatus therefor. September 23.

1891.

179. A. S. Davy. Apparatus for treating smoke and gases from furnaces and other fires. October 14.

9716. J. F. Allen. Manufacture of illuminating gas. September 30.

12,256. J. Stevenson. Transporting and delivering purifying material used in the manufacture of gas, and to apparatus therefor. September 30.

12,818. A. Hickenlooper. Gas-retort chargers. September 23.

13,506. P. Dvorkovitz. Manufacture of illuminating gas. October 14.

15,249. W. R. Lake.—From A. Hennin. Manufacture of ammonia and gas. October 14.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

15,552. R. Orr and R. M. Sutherland. Improvements in and relating to retorts for distilling shale and like minerals, and for dealing with the resulting products. September 14.

17,221. E. Binney. See Class XIII.

17,409. P. McLaren and W. L. Moore. Improvements in the manufacture of pyroligneous acid. October 13.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

15,725. S. Pitt.—From L. Cassella and Co., Germany. Improvements in the manufacture of colouring matters from amidonaphtholsulphonic acids. September 16.

16,377. H. H. Lake.—From F. Reverdin and C. de la Harpe, Switzerland. Improvements in the manufacture of colouring matter. September 26.

16,832. The Clayton Aniline Co., Limited, J. Hall, and F. Moore. The manufacture and production of artificial indigo. October 3.

16,918. O. Imray.—From The Actiengesellschaft für Anilin-Fabrikation, Germany. Manufacture of a blue colouring matter. October 5.

16,919. O. Imray.—From The Actiengesellschaft für Anilin-Fabrikation, Germany. Improvements in the manufacture of colouring matters. October 5.

17,635. C. Dreyfus. Improvements in the manufacture and production of colouring matters. Complete Specification. October 15.

17,711. J. R. Geigy. Production of violet black colouring matters or dyes. October 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,743. W. Davison. Colours or pigments for making imitation metallic and coloured enamels, paints, and printing inks. September 23.

17,712. B. Wilcox.—From F. Bayer and Co. Manufacture and production of new derivatives of alizarine and its analogues. September 23.

18,527. O. Imray.—From La Société L. D. Huguenin and Cie. Process and apparatus for the manufacture of ultramarine. September 30.

18,623. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co. Manufacture of colouring matters. September 30.

19,065. S. Pitt.—From L. Cassella and Co. Production of sulphonated thionines, and dyestuffs therefrom. September 30.

19,330. S. Pitt.—From L. Cassella and Co. The preparation of colouring matters with gamma-amido-naphthol-sulphonic acid. September 30.

20,845. H. H. Lake.—From Wirth and Co., agents for Halle and Co. Manufacture of colouring matters. September 30.

1891.

13,693. A. Lembach, U. Schleicher, and C. J. Wolff. A new soluble quinoline derivative. September 13.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

15,608. J. R. Garratt and W. Scott. An improvement in the preparation of flax yarn for weaving. September 15.

15,808. A. S. Oetzmann and S. J. Narracott. Improvements in the manufacture of coverings for floors and other surfaces, and in apparatus used for this purpose. September 17.

16,265. H. S. Close, W. O. Roff, and F. R. Donisthorpe. Improvements in the decortication and treatment of flax, esparto grass, jute, hemp, and other like vegetable fibres. September 21.

16,266. H. S. Close, W. O. Roff, and F. R. Donisthorpe. Improvements in the decortication and treatment of reha or ramie grass or fibre, and other like vegetable fibres. September 24.

16,554. W. Ross. Improvements in the process of cleansing cotton seeds and recovering the by-products therefrom. September 29.

17,081. R. Scott and W. J. Beard. Improvements in the manufacture of floorcloth and like fabrics, and machinery therefor; the improvements being also applicable to other purposes. October 7.

17,120. H. A. Mansfield. A method of and apparatus for manufacturing inlaid coloured linoleum and other materials. October 8.

17,325. G. E. Armstrong. Improved composition for treatment of fibres. October 12.

17,562. C. Hleson. Improvements in apparatus for gassing silk and other yarns. October 14.

17,642. F. J. H. Sampson. Improvement in the treatment of reha to obtain fibre therefrom, and appliance to be used in such treatment. Complete Specification. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,284. P. W. Nicolls and J. Smith. Treatment of vegetable fibrous matters to obtain fibres therefrom. September 30.

18,585. J. Davidson. Use or application of thistle-down. September 23.

19,252. C. D. Abel. Process for cleansing or purifying woollen fabrics. October 7.

1891.

11,724. J. E. Boyce. Sizing composition for cotton yarn. October 14.

14,272. J. C. Chapman.—From the United Indurated Fibre Co. See Class XIX.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

15,743. L. Wallays and L. Nisse. A new or improved method of and apparatus for printing tissues and the like. September 16.

16,195. A. Franch. A method of and apparatus for colouring and infusing coloured designs and colours through linoleum and other floor coverings and other materials. September 23.

16,126. H. A. Mansfield. An improved method of colouring and infusing coloured designs upon and through linoleum and other materials. September 23.

16,463. D. Stewart. Improvements in apparatus for bleaching or dyeing textile materials and fabrics, or otherwise treating the same with liquids or gases. September 29.

16,700. O. Imray.—From H. W. Wilson, France. Improvements in the bleaching of vegetable textile materials. October 1.

16,725. S. D. Keene. Improvements in bleaching fibrous and other materials, and treating, charging, saturating, or impregnating materials or articles with liquids either simple or containing materials or substances in solution or suspension. October 2.

17,082. H. H. Lake. From K. Oehler, Germany. Improvements relating to the dyeing or printing of woollen and other goods. October 7.

17,624. G. W. Longfield. Improvements in means or apparatus for dyeing samples, patterns, and the like. October 15.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

15,948. M. N. d'Andria. Improvements in the manufacture of ammonium chloride and other bye-products. September 14.

15,644. C. Glaser. Improvements in and relating to the art or process of manufacturing phosphoric acid from phosphate material. Complete Specification. September 15.

15,651. G. H. Gray. An improved process for converting strontium sulphate into strontium carbonate, and the manufacture of caustic alkalis. September 16.

15,822. F. H. Gossage. An improved method for obtaining mono-carbonates from bicarbonates of the alkalis. September 18.

15,833. J. M. Milnes and A. Milnes. Improvements in the apparatus for the manufacture of bleaching powder chloride of lime, or similar commodities. September 18.

15,989. C. Polony. An improved process and apparatus for decomposing alkaline salts, particularly for the production of caustic soda, caustic potash, and the carbonates of the same. Complete Specification. September 21.

16,542. R. F. Chittell. Improvements in the manufacture of nitric acid. September 29.

16,647. A. Bouke and F. G. A. Roberts. Improvements in the manufacture of acid sulphates. October 1.

16,666. R. H. Asmans. See Class I.

16,684. C. A. Burghardt. See Class X.

17,130. L. Perez Gutierrez. A process for moulding common salt (chloride of sodium) by melting it previously. Complete Specification. October 8. Date applied for March 28, 1891, being date of application in Spain.

17,185. T. Scott. Improvements in evaporating pans for the manufacture of salt from sea water or brine, and for other like purposes. October 9.

17,298. Brin's Oxygen Co., Lim., and K. S. Murray. Improvements in the preparation of anhydrous oxide of barium or other substances of like properties for use in the separation of oxygen and nitrogen of atmospheric air. October 10.

17,329. M. N. d'Andria. Improvements in the manufacture of nitrate of ammonia and other bye-products. October 12.

17,659. P. de Wilde, A. Reyelder, and F. Hurter. Improvements in apparatus for the manufacture of chlorine. October 15.

17,745. F. M. Lyte and C. H. M. Lyte. Improvements in the production of chlorine, the purification of lead, and the production of soft-burnt magnesia. October 16.

17,796. G. F. Brindley. New solid compounds of sulphur, trioxide, water, and the bisulphates or acid sulphates of sodium or potassium. October 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

14,931. J. H. Parkinson. Method of producing a porous mass of permanganate of potash. September 23.

16,233. H. C. Ball. Processes for the manufacture of sulphate of lead, and apparatus therefor. October 14.

20,074. A. Campbell, W. Boyd, and A. J. Kirkpatrick. Treatment of crude bicarbonate of soda to obtain caustic soda, carbonic acid, and other products. October 21.

21,217. C. W. Heaton. Treatment by the Claus process of gases containing sulphuretted hydrogen, and recovery of valuable products therefrom. October 14.

1891.

891. O. Imray.—From The Farbwerke Greisheim-on-Maine, W. Notzel and Co. Process for obtaining pure nitric acid direct in nitric acid reaction apparatus. October 14.

3230. J. Aseough. Manufacture of sodium borate of borax, sodium crystal carbonate, or soda and other compounds containing sodium or boron, or both. October 14.

10,202. H. H. Lake.—From The Kayser Patent Co. Manufacture of caustic alkali, carbonates of the alkaline metals and muriatic acid, and of bricks, cakes, and blocks for use therein, and apparatus therefor. October 14.

14,944. H. Walter and E. Benig. Lead chambers used in the manufacture of sulphuric acid. October 14.

15,136. F. Fichstädt. Process for the production of caustic alkali, carbonate of alkaline metals, and useful bye-products. October 14.

15,251. C. G. Collins. Process for purifying brine. October 14.

15,644. C. Glaser. Improvements in and relating to the art or process of manufacturing phosphoric acid from phosphate material. October 21.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

15,586. T. Knight. Improvements in the manufacture of earthenware jugs, cups, and such like vessels. September 15.

15,784. E. Leak. Improvements in thimble pins for supporting earthenware while being fired. Complete Specification. September 17.

15,894. H. Stephenson. Improvements in and relating to the construction of kilns or ovens for drying and burning bricks, tiles and the like. September 19.

16,005. G. Pitt. An improved mode of constructing dries for brick, terra-cotta, and other kilns. September 21.

16,137. W. Ambler. An improved method and means to be used in the manufacture of glass bottles. September 28.

16,846. D. Rylands and A. Husselbee. An improved process for lining metallic or other vessels or tubes with glass. October 3.

17,126. J. Slater and J. J. Royle. Improvements in treating china, earthenware, and other like surfaces for various useful and ornamental purposes. October 8.

17,443. W. Goodman. Improvements in the manufacture or production of marbled glass. October 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

16,131. J. W. Payne. New or improved portable or fixed continuous firing kiln for burning and staining glass, china, tiles, and enamels. September 30.

17,068. J. P. Guy. Machines for pressing and making hollow earthenware articles. October 21.

19,532. D. Rylands. Manufacture of glass and other ware, and of the caps for such ware. October 21.

20,240. F. E. Grant. Process relating to the application of coloured designs to vitreous surfaces, and machinery therefor. October 14.

20,421. D. Rylands and B. Stoner. Manufacture of glass taps and glass tees and other hollow ware. October 21.

1891.

14,076. J. Sherwin. The encaustic method or process of decorating tiles, plaques, and other articles of earthenware, china, and stoneware. September 30.

15,784. E. Leak. Improvements in thimble pins for supporting earthenware while being fired. October 21.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

APPLICATIONS.

16,005. G. Pitt. *See Class VIII.*

16,137. J. T. Welch and W. J. Owen. Improvements in the utilisation of granite and other kindred rocks in the manufacture of bricks, tiles, and other articles. September 23.

16,200. H. Ratcliffe. Improved decorative or ornamental wallings, ceilings, and the like. September 24.

16,375. W. R. Taylor. Improvements in or connected with and apparatus for the burning of cement-making materials, lime, chalk, and the like. September 26.

16,860. S. de la G. Williams. Improvements in kilns for burning lime or cement. October 3.

17,050. J. U. Robertson.—From C. W. Kennedy, United States. *See Class XIII.*

17,135. A. T. Hall. Improvements in or relating to the manufacture of concrete and similar slabs or blocks for paving and other purposes, and in means therefor. October 8.

17,466. T. A. Lee. Improvements in fireproof floors and roofs. Complete Specification. October 13.

17,556. C. Cancellieri. An improved composition for paving, flooring, building, and like purposes. October 14.

17,632. E. Edwards.—From O. Terp, Germany. Improvements in the manufacture of artificial stone. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,782. J. F. Chiverall and A. Chiverall. Manufacture of imitation stone, slate, marble, and wood. October 14.

1891.

12,219. W. J. Reagan and R. R. Longley. Composition of matter for plastering walls. September 30.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

15,566. E. B. Parnell. Improvements in or relating to amalgamators for use in the treatment of metalliferous ores. September 14.

15,567. E. B. Parnell. Improvements in furnaces for treating ores. September 14.

15,744. E. L. Mayer. Improvements in or connected with the extraction and recovery of gold. September 16.

15,745. F. J. Clinch-Jones and J. Gardiner. Improvements in metallurgical furnaces and in the use of heat radiated or resultant therefrom. September 17.

15,782. G. L. Addenbrooke. Improvements in alloying aluminium with other metals. September 17.

15,892. R. Starke and W. Paterson. Improvements in the extraction of metals from ore. September 19.

15,893. R. Starke and W. Paterson. Improvements in the extraction of metals from ore. September 19.

16,178. C. Walrand and E. Legénisel. Improvements in the treatment of steel, and in apparatus therefor. September 23.

16,192. F. Edwards.—From H. Schoenwaelder, Germany. Improvement in Siemens-Martin furnaces. Complete Specification. September 23.

16,273. J. H. Bibby. Improvements in the process of smelting copper ores and in furnaces or apparatus applicable therefor. September 24.

16,274. J. H. Bibby. Improvements in reverberatory or other furnaces for treating copper, copper ore and certain other metals. September 24.

16,348. J. J. Shedlock and T. Denny. A process and apparatus for extraction of metals from ores. Complete Specification. September 26.

16,486. L. L. Burdon. Improvements in the manufacture of seamless compound ingots and wire. Complete Specification. September 29.

16,544. H. H. Lake.—From H. A. Harvey, United States. Improvements in the manufacture of armour plates. Complete Specification. September 29.

16,683. C. A. Burghardt. Improvements in the production of alkaline solutions of zinc or tin from their respective ores. October 1.

17,224. C. Simmons. Improvements in the method of and apparatus for casting a steel block or ingot with a hole therethrough. October 9.

17,315. J. H. Pratt. New or improved metallic alloys. October 10.

17,450. L. A. Pelutan. An improved process of treating copper ores and mattes. October 13.

17,527. J. H. Noad. An improved process for the recovery of tin from tinued iron scrap or waste cuttings, and zinc from galvanised iron at the same operation. October 14.

17,621. H. W. Wallis. Improvements in the concentration of pyritic ores. October 15.

17,636. F. Webb. Improvements in means or apparatus for extracting precious metals from their ores. October 15.

17,745. F. M. Lyte and C. H. M. Lyte. *See Class VII.*

17,755. J. B. Alzugaray. Improvements in basic furnace lining and basic material. October 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

- 14,658. J. E. Hall. Manufacture of steel. September 23.
 17,173. J. C. Bull. Refining copper. September 30.
 18,235. W. D. Bohm. Separation of gold from ores or materials containing it. September 23.
 18,718. D. Jenkins. Apparatus to be employed in coating metal sheets or plates with tin or other metal or alloy. October 7.
 19,734. J. A. Johnson.—From A. Imbert and G. Jullien. Manufacture of iron and other metals, and apparatus therefor. October 7.
 19,910. J. Heydon. Means and apparatus for making the moulds in which metals are to be cast. October 7.
 20,393. H. C. S. Dyer. Manufacture of steel. October 21.
 20,415. H. R. Haigh. Construction of furnaces for puddling, heating, &c. October 14.

1891.

210. T. Langer. Improved fusible mass for case-hardening purposes. October 21.
 2049. E. Edwards.—From E. Honold. Process and apparatus for desilverising lead. September 30.
 2673. J. H. Darby. Manufacture or purification of steel or homogeneous metal. October 21.
 6303. J. H. Darby. Manufacture of steel. October 21.
 12,116. H. H. Lake.—From J. C. Pennie. Apparatus for disintegrating ores, &c. for the purpose of separating metals and metallic compounds from their gangue. October 21.
 13,739. C. James. Treating plumbiferous copper mattes and ores. October 21.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

- 15,575. A. de Meritis. Improvements in galvanic batteries. September 14.
 15,597. C. U. Fisher.—From R. H. Thompson, United States. An improved battery. Complete Specification. September 15.
 15,621. S. C. C. Currie. Improvements in the method of making the plates or elements of a secondary or storage battery. Complete Specification. September 15.
 16,270. W. P. Thompson.—From F. Correns, Germany. Improvements in or appertaining to accumulators for the storage of electric currents. September 24.
 16,487. H. H. Leigh.—From J. B. Gardiner, United States. Obtaining a fluid for primary batteries and of recovering the effective matter from the spent fluid. Complete Specification. September 29.
 16,522. W. P. Thompson.—From C. L. Coffin, United States. Improvements in or relating to electrically soldering or brazing metal. Complete Specification. September 29.
 16,667. H. Williams and W. Hepworth-Collins. Improvements in the method of and means for manufacturing nickel tubes, rods, and other bodies by electrical deposition. October 1.
 16,934. H. H. Lake.—From P. Kennedy and C. J. Diss, United States. Improvements in secondary or storage batteries. October 6.
 16,938. H. H. Lake.—From P. Kennedy and C. J. Diss, United States. Improvements in secondary or storage batteries. October 6.

17,003. A. F. Madden. Machines for making grids for secondary batteries. Complete Specification. October 6.

17,160. H. H. Lake.—From La Société dite Electriciteits-Maatschappij (Système de Khotinsky), Germany. Improvements in and relating to electric accumulators. October 8.

17,126. E. Andreoli. Generating ozone by electricity. Complete Specification. October 13.

17,430. D. M. Lamb. Electric batteries. Complete Specification. October 13.

17,655. G. D. Burton, A. H. Eddy, and G. T. Briggs. Improvements relating to the heating of metals by electricity and to machines therefor. Complete Specification. October 15.

17,725. A. P. Morrison, J. Hirschfeld, and W. Wright. Improvements in battery compounds. October 16.

17,758. The Mining and General Electric Lamp Company, Limited, and J. T. Niblett. Improvements in elements for secondary batteries. October 17.

17,808. A. J. Boulton.—From H. L. H. Maugras, France. Improvements in electrical accumulators or storage batteries. October 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

- 16,747. J. R. Thame. Manufacture of electrical insulating materials. September 30.
 19,344. E. Placet and J. Bonnet. Improvements in electrolysis in general, and particularly in electrolysis of metals. September 30.
 19,650. Siemens Brothers and Co.—From Siemens and Halske. Distribution of electricity through accumulator batteries. October 21.

1891.

9683. T. J. D. Rawlins and A. Walker. Electric primary batteries. October 21.
 10,347. D. Fitzpatrick. Electric battery. September 23.
 12,898. T. Parker. Means for the electrical deposition of copper. October 14.
 15,597. C. U. Fisher.—From R. H. Thompson. Improved galvanic battery. October 21.
 15,621. S. C. C. Currie. Improvements in the method of making the plates or elements of a secondary or storage battery. October 21.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

- 15,538. W. K. Marsden. An improved oil-press wrapper or envelope. September 14.
 15,547. J. Alexander and Co., Lim., and H. de Laspée. Improvements in the manufacture of soap and saponaceous compounds. September 14.
 16,034. R. Hutchison. Improvements in the manufacture of lubricants. September 22.
 16,552. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes, France. Improvements relating to the purification of the residues or cakes obtained from fatty substances, oleaginous fruits, or grains. September 29.
 16,557. W. R. Hodd. The manufacture of an improved soap. September 29.
 17,410. R. E. Dewhurst. Improvements in the manufacture of a new soap for general purposes. October 13.
 17,440. J. Templeman. Improvements in and relating to the manufacture of soaps and saponaceous compound. October 13.

17,482. A. F. St. George. An improved method of and apparatus for the boiling and refining of linseed and other oils employed in varnishes and for other purposes. October 14.

17,528. A. F. St. George. An improved method of and apparatus for removing or deriving glycerin from fats, oils, greases, and the like materials, and refining the glycerin derived therefrom. October 14.

17,553. H. H. Lake.—From J. Ketchum, United States. An improved lubricating compound for the chains and bearings of cycles and for other purposes. Complete Specification. October 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

17,160. E. Hermite, E. J. Paterson, and C. F. Cooper. Process for bleaching palm oil and other vegetable oils. September 23.

1891.

14,365. O. K. Thomassen. Apparatus for purifying waste oil. October 14.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

15,767. L. Ingram and T. Allwood. A composition for laundry purposes, and means for containing and applying the same. September 17.

15,791. S. Banner. Improvements in substances applicable for varnish, paint, and other things, and in the method of manufacturing the same. September 17.

15,995. R. C. Anderson. An improved manufacture of paints or varnishes for coating leather, cloth, and other materials. September 21.

16,058. J. C. Martin. Improvements in the manufacture or treatment of lead pigments. September 22.

16,098. J. C. Fell.—From C. A. Stevens, United States. Improvements in the manufacture of white lead. Complete Specification. September 22.

16,129. F. J. Rowan and B. Dawson. Improvements in apparatus for oxidising lead sulphide and zinc to form white pigments. September 23.

16,331. S. Banner. Improvements in or appertaining to varnishes, paints, drying oils, or the like. September 25.

16,582. I. Frankenburg. Improvements in the manufacture of aniline lakes suitable for the manufacture of india-rubber cloth and other purposes. September 30.

16,837. T. A. Eggestorff. Paste ultramarine laundry blue in tins. October 3.

17,050. J. F. Robertson.—From C. W. Kennedy, United States. Improvements in processes for making plastic compounds or compositions. October 7.

17,221. E. Binney. Apparatus for the manufacture of lamp-black, carbon-black, &c. Complete Specification. Filed October 9. Date applied for March 9, 1891, being date of application in United States.

17,566. C. Dreyfus. Improvements in the manufacture of coloured rubber goods or rubber-coated goods, and a material or preparation to be used in the said manufacture. Complete Specification. October 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

17,197. C. A. Fawsitt. Compounds to be used in vulcanising rubber and other substances or compounds. October 7.

1891.

9231. R. Haddan.—From A. Grammont. Method and apparatus for purifying gutta-percha. October 7.

13,513. M. E. Dejoue. Anti-fouling compounds for ships' bottoms and other purposes. September 23.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

15,661. J. de Hesselde. A new or improved method and apparatus for shrinking leather by means of fat. Complete Specification. September 15.

17,544. A. M. Clark.—From L. Starck and Co., through their agents, Wirth and Co., Germany. Improved tanning process. October 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,385. L. A. Groth. Process and apparatus for tanning hides and skins. October 7.

1891.

10,596. B. Cannon and W. J. Cannon. Treatment of size, glue, and gelatin. September 23.

XV.—AGRICULTURE AND MANURES.

APPLICATIONS.

16,281. B. L. Fletcher and J. Hoyle. Improvements in the method of and apparatus for treating or drying artificial manure, also applicable for drying grain, minerals, and other substances or materials. September 25.

17,754. J. B. Alzugaray. Improvements in insecticides and manures. October 16.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

16,164. D. Stewart. Improvements in apparatus for extracting juice from sugar canes. September 29.

17,274. R. W. Deacon.—From W. Maxwell, Java. Improvements in multiple effect apparatus for evaporating or concentrating sugar juice and other liquids. October 10.

17,753. W. Marshall. Improvements in or relating to the utilising of gluten obtained as a bye-product in the manufacture of starch. October 16.

COMPLETE SPECIFICATION ACCEPTED.

1890.

21,101. F. W. Tompson. Manufacture of invert sugars. October 21.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

15,923. A. Deininger. Improvements in malting apparatus. September 19.

16,360. R. N. Hendrie and J. Renison. Improvements in the manufacture of alcoholic spirits, beer, and stout. October 6.

17,371. J. Takamine. Improvements in the production of alcoholic ferments. Complete Specification. October 12.

17,395. J. Hillyard and E. Dugdale. Improvements in the manufacture of beer and porter or like beverages. October 13.

17,558. H. A. Snelling. Improvements in the manufacture of spirits. October 11.

17,681. R. H. Leaker. An appliance for distributing and aerating brewers' wort. Complete Specification. October 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,708. J. Cox. Brewing beer. September 23.

20,073. R. Genge and Sigmund Bros. Production of dry yeast, cattle food, and spirit from vegetable products containing starch. October 21.

1891.

5700. J. Takamine. Production of ferments and of fermented alcoholic liquors. October 21.

13,047. W. Dawson. Improvements in distillers' safes; applicable for check sampling the spent wash at outlets of "patent" stills, and for taking and testing samples of liquids generally at different times or stages of manufacture. September 23.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

15,580. V. C. H. Jessen. Improved method of preserving eggs and other articles of food. Complete Specification. September 11.

15,720. L. Rickett and F. Hyatt. Improvements in bread and in the process of treating, combining, and manipulating its materials (including cake materials and the like), and in raising or leavening and baking the same. September 16.

15,955. W. Mackean and C. Boothby. New method for preserving eggs. September 21.

15,992. Denayer's Peptonoids and Extract Meat Co., Ltd.—From V. F. Denayer, Belgium. An improved preparation of meat and method of making same. September 21.

16,181. J. T. O'Callaghan. Improvements in the utilisation of malt and germ of wheat for use in bread, biscuits, pastry, confectionery, and beverages. September 29.

16,764. W. Garden. Improvements in the preservation of fish and the like. October 2.

16,765. J. J. Clark. Improvements in non-farinaceous bread, biscuits, and other articles of food. October 2.

16,787. A. Cortaz. Improvements in milk sterilisers. October 2.

16,909. A. D. McKay. An improved medicinal food. Complete Specification. October 5.

17,363. P. Meyer. See Class XX.

17,646. W. Cole. Improvements in the manufacture of butter, and in apparatus thereof. October 15.

17,717. B. J. B. Mills.—From A. M. de la Vieuville, France. An improved process for preserving eggs. Complete Specification. October 16.

B.—Sanitary Chemistry.

16,271. A. J. Boulton.—From C. Lafforgue, France. Improvements in or relating to the purifying and separating of solid and liquid waste matter in sewage. September 24.

16,968. J. Howden. Improvements in and connected with destructors or furnaces for destroying refuse. October 6.

17,052. J. Johnston. An improved method for destroying smoke. October 7.

17,275. T. B. Wilson. Improvements in the utilisation of sewage sludge and in the production of filtering and purifying material therefrom. October 10.

17,623. W. H. Bowers. See Class I.

17,769. E. Grimshaw. A new or improved compound for the precipitation and purification of sewage, and other waste water, and drinking water. October 17.

C.—Disinfectants.

15,842. C. H. Busse. Improvements in disinfectants. September 18.

17,208. G. Spencer. A new or improved disinfectant block. October 9.

17,421. H. B. Thornton. Improvements in or relating to the manufacture of disinfectant tablets, blocks, or the like for use in water-closets, urinals, drains, and other places or articles. October 13.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

6417. A. J. Boulton.—From J. J. Sheppard. Treatment of cereals for food and other purposes, and apparatus therefor. October 21.

13,369. G. C. Dymond.—From T. B. Taylor. New cereal food, and method of manufacturing same. September 23.

11,521. J. Falcimagne. Preservation of meat, and apparatus therefor. October 7.

15,580. V. C. H. Jessen. Improved method of preserving eggs and other articles of food. October 21.

B.—Sanitary Chemistry.

1890.

18,983. W. E. Adney. Purification of sewage and other waste liquors, and the recovery of ammonia therefrom. September 30.

1891.

11,716. E. Christfield. Purification of sewage, consumption of town refuse, and utilisation of both for obtaining motive power, and apparatus therefor. September 30.

13,757. A. Mylins. Purifying sewage, waste water, and other liquids, and apparatus therefor. September 23.

13,758. A. Mylins. Sterilising liquids, particularly sewage, and apparatus therefor. September 23.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

16,839. A. S. Caldwell. Improvements in preparing materials for making paper and in apparatus therefor. October 3.

16,921. A. Bürkel and C. Osterwald. New manufacture of composition for blotting or absorbing liquids. Complete Specification. October 5.

17,522. W. Andrew. Improvements in boilers or digesters used in the manufacture of paper pulp. October 14.

17,536. S. Edwards. Improvements in corrugated paper, and in the manufacture of the same. October 14.

17,543. A. Vincent. Improvements in note paper to be used in writing and blotting pads in portfolios. October 14.

17,611. C. G. Moor and J. Nall and Co., Limited. Improvements in the process of and apparatus for obtaining chemical products from waste wood and sawdust. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,868. C. R. Bonne.—From P. Huuacus. Manufacture of celluloid articles. October 14.

18,838. A. A. Haigh. Waterproof paper. September 23.

19,545. J. W. Bretherick. Machines or appliances used in the manufacture of paper. September 23.

1891.

14,032. J. D. Tompkins. Treatment of vegetable fibre for pulp manufacture. September 23.

14,272. J. C. Chapman.—From the United Indurated Fibre Co. Composition of matter for waterproofing pulp and other fibrous articles. October 7.

14,756. C. Schœnfelen. Process and appliance for producing fine granulated paper with uniform grain of pyramidal shape. October 7.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

16,371. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of tropine. September 26.

16,552. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes, France. See Class XII.

17,137. O. Imray.—From La Société de Laire et Cie., France. Manufacture of vanilloyl carbonic acid and of vanilline by its transformation. October 8.

17,209. A. E. Wright. A new and improved preparation for use as a styptic. October 9.

17,363. P. Meyer. Improved apparatus for the production of dry extract of coffee or tea. October 12.

17,444. A. Reyehler. Improvements in the manufacture of carvacrol. October 13.

17,493. A. Bang.—From G. A. Dahl, Germany. A new anti-pyretic and anti-neuralgic chinolin derivative (to be called "Analgen-Dn-Vis") and process for the production of the same. Complete Specification. October 14.

17,654. C. D. Hellström. Improved method of and apparatus for extracting fatty particles from emulsions. Complete Specification. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

19,074. J. Y. Johnson.—From F. von Heyden. Manufacture and production of medicinal compounds for ethereal oils. September 23.

20,264. J. Bertram. Processes for obtaining the two isomeric monomethyl-ethers of protocatechuic aldehyde. October 21.

1891.

14,224. P. Ernert.—From P. Ernert. Process for the preparation of phenylester salicylic acid or salol from salicylic acid. September 30.

15,514. S. Pitt. From R. Pietet and Co. Purification of chloroform. October 21.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

15,963. E. J. Browne. A photo-mechanical process of reproducing by chemical action pictures in half tones and set in Prussian blue and other dyes. September 21.

16,072. R. Bird. An improved photographic process and apparatus therefor. September 22.

16,094. V. Mathieu. A new or improved process for producing photographic pictures, having colours resembling those of the objects from which they are obtained. Complete Specification. September 22.

16,125. A. Hill. Enlarging photographic gelatin films by the aid of chemical means and without the aid of enlarging apparatus. September 23.

16,698. W. H. Caldwell. Improvements in sensitive materials for photographic purposes. October 1.

16,857. J. Hauff. The preparation of alkylised ortho- and para-amido-phenols as developing means in photography. October 3.

17,143. A. Brin. Improvements in photography and in photographic apparatus. October 8.

COMPLETE SPECIFICATION ACCEPTED.

1890.

19,402. A. W. Scott. Method and apparatus for producing photographs, and in displaying them or the like. October 14.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

11,326A. W. E. Gedge.—From The California Explosive Co., United States. A novel explosive compound. Filed September 29. Previously included in No. 11,326, and therefore dated July 3, 1891.

15,569. J. R. Powell. Improvements in miners' squibs. Complete Specification. September 14.

16,972. G. McDonald. Improvements in fuses or shell exploders. October 6.

17,102. A. Guinard and G. Bonjour. A new or improved smokeless powder for smooth-bore and rifled guns. October 8.

17,319. W. E. Fidler. A new or improved detonating fog-signalling apparatus and detonators for use therewith for signalling on railways. October 12.

17,826. O. Imray.—From F. A. Spiecker, Germany. An improvement in the manufacture of cordite and like explosives. October 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,472. G. Trench. Explosives. September 30.

1891.

13,612. B. Kron. Centrifugal machine for separating acid from nitro-cellulose. October 21.

15,569. J. R. Powell. Improvements in miners' squibs. October 21.

PATENTS UNCLASSIFIABLE.

APPLICATIONS.

15,613. A. J. Boulton.—From O. Korschelt, Germany. A new process and apparatus for utilising the vis viva of the ether. Complete Specification. September 15.

16,426. C. J. Price. A novel method of treating waste products of hat manufactories for their utilisation. September 28.

16,910. E. Dean. A new or improved manufacture of eucalyptus products for various useful purposes. Complete Specification. October 5.

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 11.—VOL. X.]

NOVEMBER 30, 1891.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond, F.R.S.
Wm. Crowder.	Dr. Hugo Müller, F.R.S.
James Duncan.	B. E. R. Newlands.
Dr. John Evans, F.R.S.	J. C. Stevenson, M.P.
David Howard.	A. Norman Tate.
S. H. Johnson.	Sir John Turney.

Ordinary Members of Council:

A. H. Allen.	E. K. Muspratt.
Arthur Boake.	T. L. Patterson.
Jno. Calderdrey.	Boverton Redwood.
Dr. Charles Dreyfus.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.
Prof. R. Meldola, F.R.S.	William Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. F. Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

NOTICES.

Foreign and Colonial Members are hereby advised that the subscription of 25s. for 1892, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation should reach the General Secretary not later than January 15th, 1892.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 11 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, January, February, and April 1886, and February 1889. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 23rd NOVEMBER 1891.

Bedford, Jas. E., Messrs. Wood and Bedford, Kirkstall Road, Leeds, manufacturing chemist.

Biggart, Wm. L., Woodbine, Bridge of Weir, N.B., public analyst.

Cowper-Coles, Sherard Osborn, London Metallurgical Co., Ltd., 80, Turnmill Street, E.C., manager.

Cunningham, H. D., Alkaline Reduction Syndicate, Ltd., Hebburn-on-Tyne, manager.

Dewilde, Prof. P., 339, Avenue Louise, Brussels, professor of chemistry, University of Brussels.

Fowler, Gilbert J., Dalton Hall, Victoria Park, Manchester, assistant demonstrator in chemistry.

Garçon, Prof. Jules, 13, Boulevard de Latour Maubourg, Paris, professor of chemistry.

Gardner, Walter M., Yorkshire College, Leeds, lecturer on dyeing.

Harper, Prof. D. N., St. Anthony Park, Minn., U.S.A., professor of agricultural chemistry, University of Minnesota.

Hersam, Ernest A., Mass. Inst. of Technology, Boston, Mass., U.S.A., assistant in sanitary chemistry.

Knaggs, Alfred B., Yorkshire College, Leeds, student of science.

Lee, Theophilus H., Edgcombe Villa, Clevedon, Somerset, analytical chemist.

Marshall Jno., Messrs. Marshall, Son, and Co., Cudbear Street, Hunslet, Leeds, manufacturing chemist.

Martino, F. W., 6, Tiptonville, Broomhill, Sheffield, German silver manufacturer.

Miller, Jno., Messrs. Jas. Black and Co., 23, Exchange Square, Glasgow, calico printer.

Morris, Herbert E., Fernlea, Priory Road, Sale, Cheshire, analytical chemist.

Myers, Wm. S., 7, Museum Mansion, Great Russell Street, London, W.C., student.

Reibstein, Dr. Tuisco, 232, Rue de la Poste, Brussels, chemist "Société Generale de Maltose."

Richardson, Walter W., 1, Montpellier Terrace, Cliff Road, Leeds, manufacturing chemist.

Shepherd, Jos., 71, Albion Street, Leeds, civil engineer.

Thornton, Christopher, Allen's Printworks, Providence, R.I., U.S.A., assistant manager.

Thornton, David H., 21, White's Terrace, Manningham, Bradford, dyer.

Watney, Thos. S., 71, Albion Street, Leeds, electrical engineer.

Whitelaw, T. N., 87, Sydney Street, Glasgow, soap manufacturer.

Williams, Percy B., Felbrigg, The Bank, Highgate, N., chemical student.

Woolworth, L. G., 246, Fountain Street, Providence, R.I., U.S.A., chemist.

CHANGES OF ADDRESS.

Archbold, Dr. G., Journals to 1224, B. Street S.W., Washington, D.C., U.S.A.

Banks, Jno. H., 10, East 49th Street; c/o Ricketts and Banks, 101, John Street, New York.

Meeting held Monday, November 2nd, 1891.

MR. THOMAS TYRER IN THE CHAIR.

VOLATILE ORGANIC MATTER IN POTABLE WATER AND A SIMPLE METHOD OF ESTIMATING DISSOLVED FIXED AND VOLATILE ORGANIC MATTER IN WATER.

BY W. C. YOUNG, F.R.C., F.C.S.

Consulting Chemist to the Lea Conservancy Board, &c.

THE presence of volatile organic matter in potable water has long been suspected, but with the exception of some experiments by Tiemann and Preusse (*Chem. Soc. J.* **38**, 29), little has been done to prove its existence.

Frankland, in his book on water analysis, gives directions for the preparation of distilled water free from organic matter, thereby implying the probability of its presence in distilled water prepared in the ordinary way. More recently Berthelot and André (*Chem. News*, **63**, 176), have shown that the peculiar odour emitted by garden soil after a summer shower is due to volatile organic matter, and Phipson (*Chem. News*, **63**, 179) has confirmed this, and stated further that chalk and other porous rocks, &c. give a similar odour when moistened, which is due to the same cause. This being so, the presence of volatile organic matter in natural waters may reasonably be expected, and further, the products of fermentation being largely volatile and soluble compounds, it would seem that all waters polluted by decomposing organic matter must necessarily contain volatile organic matter.

In the course of some experiments on a new method of estimating organic matter in water, I made some observations which indicated, beyond a doubt, the presence of appreciable quantities of volatile organic matter, and, as a result of these experiments, extending over a long period, I am now able to submit to you a process by which the actual amount of fixed and volatile organic matter may be estimated, together or separately, in a water.

As it seemed to me hopeless to attempt to separate the organic matter directly from a water residue, I directed my

attention to separating as much as possible of the other constituents and determining the organic matter in the remainder by loss on ignition. Various ways of doing this were tried, but the addition of sodium carbonate and subsequent filtration of the water after concentration by evaporation was found to be the best. In the preliminary experiments, made in this way, I found that when the sodium carbonate was added to the water, before or in the early stages of the evaporation, much more organic matter was obtained than when it was added after the water was concentrated to a small bulk. It seemed to me that the increase could only be accounted for on the assumption that volatile organic matter was present and was carried off with the steam in the absence of sodium carbonate. The fact also indicated that sodium carbonate possessed the property of fixing the volatile organic matter, and subsequent experiments, to which I shall presently refer, confirmed this.

I will not weary you by detailing the very numerous experiments which resulted in partial success or utter failure, but proceed at once to describe the process ultimately adopted. To determine the total organic matter: 1 litre of water, to which 0.5 gram of dried and ignited sodium carbonate is added, is distilled in a conical iron still of about 2 litres capacity, attached to a tin worm condenser. The distillate is received in a graduated measure and when 97.0 cc. has been collected the heat is removed, the still disconnected, the contents and washings placed in a platinum basin and evaporated to dryness on a water-bath. The residue is then dissolved in a little pure distilled water, filtered through an asbestos plug into a platinum basin, dried on a water-bath, and subsequently heated for an hour in an air-bath at 150° C. After cooling thoroughly in a good desiccator, the basin and contents are weighed in a quick balance. The residue is then ignited at a low temperature, cooled, and weighed, and the loss noted. The ignited residue is then dissolved in water, excess of sulphuric acid added, and standard solution of potassium permanganate (1 cc. = 0.0001 gram O) added until the colour remains permanent after five minutes. The weight of oxygen lost, thus ascertained, is deducted from the loss on ignition and the difference is the organic matter. To determine the fixed organic matter the same course is followed, except that the sodium carbonate is not added until the concentrated water is transferred from the iron still to a platinum basin.

To determine the volatile organic matter the distillate from the last-mentioned process is placed in the still together with 0.5 gram of sodium carbonate and distilled until about 25 cc. remains in the still, afterwards proceeding as before, except that it is unnecessary to ascertain the oxygen lost by ignition. The result represents about two-thirds of the total volatile organic matter present; further small quantities can be recovered from the distillate by repeating the process.

The asbestos used for filtering is prepared in the form of pulp. It should be white and free from hard pieces, ignited, boiled with dilute hydrochloric acid, thrown on to a funnel and washed free from acid, then boiled with strong solution of sodium carbonate, thrown on to a funnel and thoroughly washed. The filter is made by placing a small perforated platinum cone in a sheet-iron funnel, and covering it with the asbestos pulp. The asbestos is then washed down and pure distilled water passed through until the droppings are clear, when the filter is ready for use. The filter may be used repeatedly, in fact until it is completely clogged by the precipitate from the water. In the early part of this investigation an open vessel was used for evaporating the water, and the still was only employed in the first instance for the purpose of collecting the condensed water in order to see whether the volatile organic matter could be removed from it, but it was immediately seen that it was much the better method, as the evaporation was effected in less than half the time, and the water was kept from possible contamination by organic matter in the air during that part of the process.

Stills made of copper and of nickel were successively employed, but rejected as minute quantities of the metal were found in the residues. I have not yet tried platinum, but there can be no doubt it would be the best for the

purpose. The process is extremely simple, requires little personal attention, and can be completed within four hours. Having described what I may call the mechanical details of the process, I will now describe its chemical aspects. By the employment of sodium carbonate the whole of the compounds of calcium, magnesium, and iron are precipitated, and any combined ammonia in the water volatilised. There only remains sodium chloride, alkaline nitrates, and uncombined silica to interfere with the loss on ignition being accepted as a measure of the organic matter present, and neither of these compounds being present in estimating volatile organic matter the results may be accepted as free from objection on that account. As regards sodium chloride, the burning of the organic matter is so rapid (a few seconds suffices) and the heat so low that none is volatilised, repeated trials giving the same amount of chlorine in the ignited residue as was found in the water originally. But if a little is lost through excessive heating the loss can be ascertained and due correction made.

As regards alkaline nitrates, provision is made in the process for ascertaining and correcting for loss of oxygen by reduction of nitrates, but I may mention that it is seldom of any great importance and has never exceeded, in ordinary drinking waters, the equivalent of 0.07 grain per gallon. The presence of nitrates assists the burning of the organic matter very materially, and in the case of very foul waters, such as sewage effluents or seriously polluted waters, which seldom contain any, I find it advisable to add a drop or two of solution of potassium nitrate before the final evaporation. With regard to uncombined silica, I have never found it present, and if it should be I do not think the heat required to burn off the organic matter is sufficiently great to cause it to decompose the sodium carbonate.

As there was a possibility of the sodium carbonate retaining some of its combined water after heating for an hour at 150° C., I placed 0.5 gram in a platinum basin, moistened it with water, dried it on a water-bath, and subsequently heated it for an hour in an air-bath at 150° C. After cooling, the dish and contents were weighed. The sodium carbonate was then fused and the weight again taken after cooling, but no loss was observed. This experiment was repeated with the same result.

Until quite recently it was my custom, after weighing the ignited residue, to moisten it and dry, first on water-bath and then for an hour at 150° C. and again weigh, but as no difference in weight was ever noted I abandoned the practice as unnecessary. The following experiments with known weights of various soluble organic compounds show the accuracy of the process. The dried substance (with the exception of the albumen) was dissolved, together with 0.5 gram of sodium carbonate, in a litre of distilled water perfectly free from organic matter, and the process carried out as described, a little potassium nitrate having been added in each case before the final evaporation. The experiment with albumen was made as follows:—a small quantity (about 0.1 gram) of finely-powdered albumen was digested on a water-bath with 1 gram of dried sodium carbonate in 10 cc. pure distilled water, with frequent shaking, for an hour. After filtering through asbestos the bulk was made up to 20 cc. One half of this solution was evaporated to dryness on a water-bath, heated for an hour at 150° C., and the loss on ignition ascertained. After correcting for reduction of nitrate present the loss amounted to 0.01 gram. The other half was made up to a litre with pure distilled water and submitted to the process in detail.

The first column gives the non-volatile, the second the volatile, the third the sum of the two preceding, and the fourth the total organic matter obtained in one operation. These results show that volatile organic matter is present in considerable quantity in the "East London" water, exceeding that of the fixed in every case, as the figures represent not more than two-thirds of the total present. A comparison of the figures in the third and fourth columns affords a fair test of the accuracy of the process, and it will be seen that with two exceptions they agree fairly well with each other. In the next table I give the total organic matter, together with the free and albuminoid ammonia and oxygen required (Tidy's method) in a variety of waters of different degrees of purity.

The two first are exceptionally pure, although one is river water, the next two natural spring water, the two following, river water as taken by the water companies for public supply, the next three, well waters undoubtedly polluted, and the others clarified sewage waters.

From these results it appears that there is no definite relation between the oxygen required or the albuminoid ammonia and the total organic matter in solution. The samples from the source of the Lea and of the New River were taken on the 14th and 15th April 1891 respectively, and those from the intakes of the New River Water Company and the East London Water Company on the 21st April, the weather for some time previous having been fine and dry, therefore they are fairly comparable. The results obtained by this process on these samples establish the interesting fact that the water rising in the springs in Leagrave Marshes, Bedfordshire, contains more organic matter in solution than the water in the River Lea at Ponder's End after travelling about 35 miles, and also that the water of the Chadwell Spring (which is the source of the New River) contains considerably more organic matter in solution than that of the River Lea at the point where the New River Water Company draws its supply, and more than the water from the source of the Lee. In Table No. 3 I give the results obtained with some of the London water companies' water as supplied to the public during six consecutive months. The samples, which were all drawn direct from the mains, were taken at the following places:—

East London, at my laboratory, 117, Poplar High Street; New River, hydrant in Gower Street; West Middlesex, Portland Road; cab rank; Kent, Police Station, Blackheath Road.

The high figures obtained from the Kent Company's water are very remarkable, as the organic carbon results published monthly by Frankland are always very much lower from this company's water than any of the others. With this exception, these results (taking the last column for comparison) classify the four waters very much as they have been hitherto by the ordinary processes of analysis: that is to say, the "New River" and "East London" are similar in quality, the former occasionally the better, while the "West Middlesex" is (except in July) always the worst. On the other hand, the "Kent," instead of containing very much less organic matter than the others, as we have been led to suppose, contained more than the "East London" and "New River" in June, and in July more than either of the others.

Occasionally, the monthly report of Messrs. Crookes, Odling, and Tidy on the water supplied by most of the London water companies contains an estimate of the organic matter present, which appears to be obtained by multiplying the organic carbon found by 2.5. For the purpose of comparison, I have taken the organic carbon given by Frankland in his official reports to the Local Government Board, multiplied it by 2.5, and placed the results by the side of the fixed organic matter obtained by my process in some of the London companies' water (before referred to) for the corresponding months.

	Frankland Organic C. $\times 2.5$.	Fixed Organic Matter.

West Middlesex, August.....	0.222	0.357
Kent, August.....	0.077	0.232

It will be seen that although the figures in a few cases agree fairly well, in nearly every instance the "fixed organic matter" is the higher, the greatest difference being in the Kent water results.

In Frankland's and all other similar combustion processes the water is evaporated in the presence of an acid. The

experiments I have recorded indicate that the volatile organic matter in water possesses somewhat of an acid nature, and in order to ascertain whether or not the presence of sulphurous acid during the evaporation caused any loss of organic matter, I distilled a litre of East London water, to which 20 cc. of a saturated solution of sulphur dioxide had been added, in a glass retort. When the water was reduced to about 25 cc. it was transferred to a platinum basin and evaporated to dryness on a water-bath, taken up in a little water and filtered through an asbestos plug into a platinum dish. Half a gramme of sodium carbonate was then dissolved in the water, the process continued, and the loss on ignition ascertained as in the ordinary method already described. In this way three experiments gave 0.28, 0.28 and 0.42 grain per gallon respectively against 0.315, 0.322, and 0.469, obtained by evaporating without acid. It therefore appears that the presence of sulphurous acid during the evaporation causes a slight loss of the non-volatile organic matter.

By repeated distillation with sodium carbonate further traces of volatile organic matter are obtained until after the third or fourth repeat the distillate contains no more. The quantity obtained in the process described represents, in ordinary drinking waters, about two-thirds of the total quantity present. By largely increasing the quantity of sodium carbonate less organic matter is contained in the distillate, but distilled water absolutely free from organic matter on the first distillation can only be obtained by frequently agitating the water with 1 per cent. of calcium or barium hydrate and distilling after complete subsidence and separation of the precipitate.

During the last few years a large trade has sprung up in aerated waters prepared with distilled water, the manufacturers claiming, amongst other advantages, perfect purity and complete absence of organic matter. It is evident from the results laid before you that, unless special precautions are taken in its preparation, all distilled water must contain more or less organic matter in solution. Samples of aerated distilled water from two of the largest manufacturers gave the following quantities of organic matter:—

Sample A.	Sample B.
Grs. per Gal. 0.183	Grs. per Gal. 0.378
0.131	0.322

An attempt was made to substitute barium hydrate for sodium carbonate in the process, so that nothing should be present in the residue but the alkaline salts and organic matter contained in the water under examination. The method failed, but the results obtained were so very interesting that I cannot omit to mention them. The experiments were made as follows:—1.1 grms. of barium hydrate was added to 1,100 cc. of East London water, well agitated, and after subsidence 1 litre syphoned off into the still and evaporated to a small bulk. The water and washings of the still were then transferred to a platinum basin and evaporated to dryness on a water-bath, taken up in a little water and filtered through an asbestos plug into a platinum basin. Dilute sulphuric acid was then added in very slight excess, then an excess of barium carbonate, and the whole evaporated to a small bulk on a water-bath. It was then filtered through asbestos, evaporated, dried, and the loss on ignition ascertained as before described.

Two experiments gave 0.175 and 0.119 grain per gallon organic matter against 0.735 obtained with sodium carbonate.

The distillates were treated with 0.5 gm. sodium carbonate and gave only 0.035 grain organic matter per gallon in each case.

These results indicate very clearly that the organic matter present had formed an insoluble compound with the barium, and was separated in the precipitate. In order to settle this beyond a doubt a litre of the East London water giving 0.56 grain total organic matter per gallon was treated with

a gramme of barium hydrate, well shaken and, after subsidence, the clear liquid syphoned off. The precipitate with the remaining liquid, measuring about 10 cc., was then made slightly acid with dilute sulphuric acid and filtered through asbestos into a platinum dish. To the filtrate 0.5 gram. of sodium carbonate was then added, and when dissolved evaporated to dryness, taken up in a little water, filtered, again evaporated, &c., and the loss on ignition ascertained.

The result gave 0.56 grain of organic matter per gallon, or precisely the same as was found in the water by the sodium carbonate process. This experiment was repeated on another sample of water with a similar result. It is therefore very evident that the organic matter was precipitated by the barium hydrate, and I have good reason to believe that the same result is obtained by substituting calcium hydrate for barium hydrate, although I find a much larger quantity is required.

The process gives only the quantity of organic matter, and although it does not afford any direct evidence of the quality of the organic matter in water still, when there is a large quantity present, the odour given on heating enables a fair opinion to be formed as to whether it is of animal or vegetable origin. Where only small quantities are present I find it quite impossible to decide as to its origin by the odour given on heating the residue. I need hardly say that in case of doubt Wanklyn's ammonia process is capable of giving the required information.

DISCUSSION.

Mr. DAVID HOWARD remarked that he had the misfortune to live on the lower part of what was, by courtesy, called the River Lea. He could not but regard that title as a misnomer, for the stream was really a prolongation upwards of the London sewers. His experience of the stream in question had caused him to have grave doubts whether the evaporation of water in a dish by ordinary methods could be depended on for the estimation of the impurities contained in it; for he had found that, when the so-called water of the River Lea was distilled in his works, the resulting product was certainly not what one would expect a distilled water to be. One valuable result of the reading of the paper would be its tendency to dispel the common assumption that any water which had been volatilised was necessarily pure distilled water—an assumption which often led to serious errors in analytical work.

Dr. THOS. STEVENSON complimented the author on his excellent attempt to determine a very important question in the analysis of waters. He felt considerable diffidence in attempting to criticise the paper, because Mr. Young's work was practically a new departure in the treatment of the subject, and one would like the experiments to be extended over a larger number, and a greater variety of waters, before coming to any definite conclusion respecting the process. One point struck him as singular, namely, the comparison between the deep-well water supplied by the Kent Company, and the analyses of the waters from the Thames-supplied companies. Taking the first analysis given in Table 3, it seemed to him strange that the proportion of volatile organic matter in the East London water should be 0.7, while that of the New River water was 0.14, notwithstanding that the New River intake was partly from deep-well water, and partly from the same river that supplied the East London Company; while at about the same date the amount of volatile matter in the Kent water was precisely the same as that in the East London. This seemed to him to be a very striking fact. He had not himself often analysed the East London water; but taking the river-supplied water of London, and comparing with it that supplied by the Kent Company, one usually found by all the ordinary tests that the Kent Company's water was clear, destitute of colour, and contained less organic nitrogen than the Southwark and Vauxhall or the Lambeth Company's water. This general characteristic had been confirmed by the experiments; and there could be no doubt that the

waters ordinarily supplied by those two companies were more coloured, because they received more organic matter than did the water of the Kent Company. This fact forced him to take one of two alternative views. Either rivers were capable of getting rid of organic matter to a greater extent than the water from the deep beds that supplied the Kent Company, or there was some defect in the method adopted by Mr. Young. It was obvious that the method laid before them by the author was a very promising one; and he did not wish his remarks to be taken as depreciatory of Mr. Young's work. With regard to the distilled water professed to be supplied by certain aerated water companies, he could not claim to have much personal experience of the matter; but he had heard from those who had such experience that, when distilled water was used for the manufacture of aerated waters, it was necessary to filter it through animal charcoal. It was well known that distilled water, notwithstanding the utmost care in its production, usually possessed a distinctly unpleasant flavour, and as it was necessary to filter it through animal charcoal, that was probably the source of the large percentage of organic matter—exceeding the amount usually found in the ordinary water supplied to London—which Mr. Young had determined. It was within his knowledge that in some aerated waters produced from distilled water, phosphates had been found, a fact which confirmed what he had said with respect to the use of animal charcoal.

Mr. WILLIAM THORP heartily welcomed this attempt to strike out a new method of water analysis. In such cases the common difficulty was that too much attention was given to particular figures, and too little to a broad view of the case. He regarded the analysis of water as analogous to the examination of a patient by a physician, when all the symptoms and factors had to be taken into account, though any isolated facts or figures might be of very little account in themselves. This added to the difficulty of following any proposed new method, and forced one to speak of such methods, in the first instance, with great reserve. At first sight, it certainly appeared to him to be a somewhat retrograde step to attempt to determine the organic matter by ignition, as so much depended in that case on the heat and the general conditions of the process. At one time it seemed to have been thought that organic matter could be absolutely annihilated by ignition. But it was obvious that all that could happen was a decomposition of the constituents, the matter itself remaining always in actual ponderable existence in some form or other. He was surprised to see such great variation in the results obtained from the Kent Company's water. When he was concerned in water analysis, the Kent Company's water was considered almost as a sort of datum line upon which to base the comparison of other waters. But in the tables before the meeting, that water appeared to vary considerably. In March the total amount of organic matter was said to be 0.336; in June, when one would hardly expect it to be much worse, it was given as 0.616; and in July, 0.672, or twice what it was in March. But the point which most puzzled him was that the ratio between the fixed and volatile matter varied so extremely. Referring to Table 3, it would be seen that in March the fixed matter was more than four times as much as the volatile matter; but in April the two were nearly equal, the volatile matter being 0.245 and the fixed matter 0.280. In May the quantity of fixed matter was twice that of the volatile, and in June two and a half times as much, but in July the proportions were reversed, the volatile matter being estimated at 0.455 and the fixed matter at only 0.266. On the other hand, in August the fixed matter was stated as being seven times as great as the volatile matter. Of course he had no evidence whatever against these figures, but it seemed to him unlikely that water drawn from deep wells in the chalk—which would have a sort of integrating action tending to cause the water to be of an uniform composition—would be affected to any great extent by mere surface variations, such as rain or sunshine, heat and cold. It seemed highly improbable that not only the quantity but the nature of the organic matter should vary to such an extent. Perhaps the author could

offer some explanation of these points. He took it that the actual condition of the organic matter in any water was at all times extremely complex, and every process of water analysis had to face that difficulty. Therefore any attempt to get figures directly representing the quantity of organic matter must be received with very great reserve. The usual method of proceeding was either to determine the amount by ignition, or by estimating some of the individual constituents such as the carbon or the nitrogen present. The total amount of the organic matter itself was never determined. If the one method were employed, it was assumed that the total organic matter would vary in proportion to the loss on ignition. If the other, that it would vary in proportion to the carbon or nitrogen. In no case did he think actual figures representing total organic matter could be obtained; and beside all this there was the question of its nature. It seemed to him, therefore, that it was the duty of the water analyst to give due consideration to all the facts of the case, and then report whether the water was good or bad, thus fulfilling the conditions he had started with of the examination of the patient by the physician. He had been greatly interested by the paper, and feared that in criticising it with imperfect knowledge, he might perhaps have unwittingly done the author an injustice.

MAJOR FLOWER hardly felt justified in taking part in the discussion; but as the River Lea had been unfavourably referred to by Mr. Howard, he might be pardoned for reminding that gentleman that the condition of the River Lea near his works in no way affected the character of the water supply of London.

MR. DAVID HOWARD remarked that he did not intend to imply that it did.

MAJOR FLOWER, continuing, said that many people were fond of using the expression "the filthy River Lea." The bad condition of that river, however, in its lower reaches, was due to the storm-water outlets of the Metropolitan sewers at Old Ford, from which sewage poured forth to the extent of millions of gallons daily. With regard to the samples which Mr. Young had analysed, it might be interesting to record the fact that he (Major Flower) had taken those samples himself, with the intention of putting them in his evidence before the Select Committee on London Water as to the condition of the River Lea. He could not but think that the opinion which Mr. Young had given would be a sufficient answer to those people who said that the River Lea authorities sold nothing but dilute sewage to the London Water Companies.

MR. DAVID HOWARD hoped that he had not conveyed the idea that the River Lea which he knew was the River Lea that the people of London had to drink. Unfortunately for him, the people of London drank up the River Lea before it reached his works.

MR. W. C. YOUNG, in reply, said that with respect to Dr. Stevenson's wish that there had been a greater number of samples, extending over a longer period of time and a larger variety of waters, it seemed to him that he had given sufficient evidence to enable those who read the paper carefully to form an opinion of the process. They had before them the result of six months' investigation into the waters from four representative companies supplying London. In another table they had a number of samples of various qualities from a very pure water down to absolute sewage. He ventured to think, therefore, that when Dr. Stevenson should have had time to read the paper quietly, he would see that it gave illustrations of all kinds of water, and that the analyses were spread over a sufficiently long period. Dr. Stevenson had compared New River and East London water, and expected to find a difference, because the New River supply consisted of a water partly drawn from deep-well water, and partly from river water. But the East London supply was of precisely the same character. The East London Company had

supplemented their river supply by deep-well water, and were rapidly approaching the same standard as the New River Company. Dr. Stevenson's statement that distilled water had to be passed over columns of animal charcoal before being used for the manufacture of aerated waters was quite correct. Distilled water, as commonly prepared, had a very unpleasant taste, and gradually became "ropy." It was for this reason that it had to be filtered through animal charcoal. But that would not account for the organic matter contained in such waters; for, if the animal charcoal were properly prepared—and he believed that great care was exercised in preparing it—it would not be capable of adding any organic matter to the water filtered through it. It would, however, undoubtedly add phosphate, as Dr. Stevenson had said. Mr. Thorp seemed to be under an impression that the process which he (Mr. Young) had brought before the meeting was a *réchauffé* of the old "loss on ignition" process. But when Mr. Thorp had further studied the matter, he would find that it was quite a different thing from the old process that used to be relied upon. All the objections to that process were absent from the process which he had brought before them. One was compelled to estimate the organic matter by loss on ignition, for really there was no other satisfactory way of doing it, unless one determined the quantity of carbon present, and guessed at the quantity of organic matter from the carbon; but, as he had said, the present process was free from the faults hitherto connected with that method of working. With regard to the variation in the quantity of organic matter in the Kent water, he might say that he had not only ascertained the actual weight of the organic matter, but that the colour of the residue and the degree of charring was also an indication of the quantity of organic matter present. In every case in which the weight of the organic matter was low, the residue was nearly colourless and darkened little on heating and *vice versa*; so that the figures given might be said to have been confirmed by observation of the colour during the experiments. He might mention also that the whole of the experiments made on London waters had been given. Not one had been omitted. With regard to the Kent water, the organic matter present therein was evidently of a very peculiar nature, for he had noticed in comparing the results obtained by Dr. Bernays with those got by Dr. Frankland, that the former sometimes showed twice as much as the latter. It seemed to him that the only explanation of this remarkable difference was to be found in the fact that, as shown in his tables, the organic matter in the Kent water varied very considerably. There were one or two objections to the process which members either had not observed or had not referred to, and perhaps it would be well that he should mention them. Where a large quantity of nitrate was present there was, of course, the possibility of decomposition of the nitrate with production of carbonate; but the temperature required for the process was so extremely low (below red heat) that there was no fear of the decomposition of nitrate. He had made experiments, using known weights of nitrate of potash (largely in excess of the quantity present in any of the London waters) with the quantity of carbonate of soda stated in the paper, and after allowing for the loss of oxygen as ascertained by the method the difference unaccounted for was only 0.0004 grm., showing that the nitrate of potash was not converted to any appreciable extent into carbonate, as might have been expected. Then, again, with regard to the precipitate formed from the water by the carbonate of soda, it might be suggested that it contained some organic matter, but he had found by experiment that the loss on ignition of the precipitate from 10 litres of water was only 0.004 grm. In another experiment, where 0.286 grm. of the precipitate was taken, there was no loss at all, and in a third the precipitate from two litres (0.427 grm.) lost 0.002 grm. That organic matter might have been suspended in the water; but it was to be remembered that the process which was the subject of his paper took account only of organic matter in solution.

MR. WILLIAM THORP feared that Mr. Young had misunderstood his remarks about the Kent water. His doubts

referred not so much to the quantity of organic matter found in that water as to the great variation of its character. In the August sample there was seven times as much fixed matter as volatile, whereas in the previous month—July—the ratio was reversed, and there was, roughly, twice as much volatile as fixed organic matter. It seemed hardly credible that the organic matter in water drawn from very deep wells in the chalk could vary in kind to such an extent as that. Then, again, he had not referred to the number and character of the samples, because Dr. Stevenson had done so for him; but it was to be noticed that all the author's samples had been taken from the neighbourhood of London, and he thought what Dr. Stevenson meant to convey was, that it would be advisable to extend the process to the waters from some of the harder non-calcareous rocks, such as those of the Midland and Northern counties, and in this suggestion he concurred.

Mr. YOUNG remarked that he quite agreed with Mr. Thorp's latter observations.

SOME EXPERIMENTS ON PETROLEUM SOLIDIFICATION.

BY SAMUEL RIDEAL, D.Sc., F.I.C.

Lecturer on Chemistry at St. George's Hospital.

It has long been known that the mineral oils can be readily gelatinised or converted into a more or less solid mass by the incorporation of various soaps or by the action of certain saponifying substances which occur naturally, and of which the common soap wort may be taken as an example.

During the last few years several patents have been granted for different modes of applying the above general principles with a view to obtaining a solid product containing petroleum which might be of some commercial utility. When soaps are employed for the gelatinisation of the petroleum a product is obtained which has most of the properties of the soap added, and if the percentage of soap be large the mixture of soap and petroleum can be utilised as a detergent, and many of the cheaper soaps have a considerable

quantity of paraffin incorporated with them in this way. It was, however, with a view of ascertaining what was the best and minimum quantity of foreign material necessary to bring about the solidification of the petroleum that these experiments were undertaken, and as the literature on this subject is very meagre, consisting chiefly of patent specifications of inventors who for different reasons have not given a comparative statement of the properties of the different products described, it was thought that a short description of an attempt to systematise this subject would not be uninteresting to members of the Society of Chemical Industry. At the present time, to the best of my knowledge, none of these products are on the market in large quantities, but there is a good deal of private work going on, and there would seem to be no doubt that in a short time there will be industrial applications of these products.

I have grouped for convenience the more important experiments under different headings, and, while they do not pretend to be an exhaustive treatment of the subject, most of the proposed methods for effecting this object will be found to be included. In order to obtain comparative results of the different consistencies of the various products and thus form a guide for future work with those materials which give the most suitable bodies for the different purposes for which they may seem adapted, one kind of petroleum has been used throughout, and as it was a refined oil used for illuminating purposes, better products, so far as consistency is concerned, would in the majority of cases be obtained if a natural oil containing the heavier hydrocarbons were employed.

A.—Solidification by means of Soap.

It is obvious that various methods of procedure may be adopted both for making the soap and also for its incorporation with the petroleum. After several trials it was found that the most satisfactory results were obtained when the soap was actually made in contact with the petroleum, either simply by the addition of an alkali to a fatty acid dissolved in the heated oil, or by saponifying vegetable oils in intimate contact with the petroleum. As already mentioned the conditions for the best incorporation of crude paraffins as an adulterant of soaps is probably well known, although for obvious reasons there is little public knowledge of these conditions. The experiments under these headings were, however, undertaken with a different object in view, and as in only a few cases more than 10 per cent. of soap was present in the finished product, the results will have little interest to the soap maker. The chief results are embodied in the following tables:—

TABLE I.
EXPERIMENTS WITH FATTY ACIDS.

Fatty Acid.	Lime.	Dry Soda.	Aqueous Soda.	Aqueous Ammonia.	Steam.	Sodium Silicate.	Sodium Aluminate.	Litharge.	Nitrous Acid.
Stearic acid {	Soap remains partially suspended in liquid.	Translucent solid granular mass.	Granular, opaque, white firm mass.	Firm mass, opaque and white.	Translucent white jelly.	Pure white, pearly, hard mass.	Hard white translucent mass.
Oleic acid {	Stiff whitish jelly.	Stiff cream-coloured opaque jelly.	Soap formed, separates from the petroleum.	Very stiff, flexible, white jelly.	Stiff cream-coloured jelly.	Separation of cream soap from oil.	No separation of solid chloride acid.
Elaidic acid {	Soap formed, which separates.	Soap formed, which separates from petroleum.	Soap formed, which separates.

An experiment was also tried with aniline, oleic acid, and petroleum to see if a solid product would be formed, but gave a negative result. In the above experiments 10 per cent. of fatty acid was employed, and sufficient base to neutralise it subsequently added.

TABLE II.
EXPERIMENTS WITH SOAPS AND BEESWAX.

Solidifying Agent.	Water.	Cane Sugar Syrup.	Dilute Hydrochloric Acid.	Dry Soda.	Ammonia.	Sodium Silicate.	Alone.
Commercial soap.	Forms a viscous liquid in which soap is suspended.	Soap separates out and solidifies at bottom.	Soft solid flocculent mass floating in petroleum.
Dry soap.....	Hard yellow compact mass.	Soap separates out on cooling.
Beeswax.....	Soft dark brown buttery mass.	Light yellow sloppy mass.	Soft light-brown mass.

TABLE III.
EXPERIMENTS WITH OILS AND FATS.

Oil or Fat.	Aqueous Ammonia.	Aqueous Soda.	Dry Soda.	Nitrous Acid.	Sodium Silicate.	Sodium Aluminate.	Litharge.
Tallow	Remains fluid; slight separation of soap.	Separation of oil and of aqueous soap.	Fairly hard light brown mass.	Viscous liquor containing insol. soap.	Fairly hard; cream-coloured solid.
Colza oil.....	Forms a perfectly fluid mass.	Forms soap which separates from the oil.	Forms a fairly hard brown mass.
Cotton-seed oil...	Complete separation of soap from oil.	Forms a viscous semi-liquid.
Suet.....	Complete separation of the soap.	20 per cent. forms a whitish cake; some separation.	Pasty brownish mass.	Viscous liquid containing semi-solidified soap.	White soap separating from oil.
Olive oil.....	Forms an opaque milky liquid.	Gives a yellowish pasty mass.	Soft solid brownish mass like vaseline.	No separation of solid chadun.	Highly viscous liquid containing solid soap.	Stiff opaque jelly.	Separation of soap formed from petroleum.
Lard oil.....	Separation of soap from oil.	Forms a thick viscous liquid.
Castor oil.....	Hard firm cream-coloured mass.	Forms a very hard, firm mass; some separation.
Rosin.....	Rosin soap separates out entirely from oil.	Rosin soap separates out entirely.
Linseed oil.....	Very little saponification takes place.	Soft solid yellow sloppy mass.
Peanut oil.....	Complete separation of white soap from oil.	Saponifies white, hard, and firm mass.	Fairly hard mass, white and opaque.

From the above tabular statements it will be seen that the hardest products at the ordinary temperature and those which are most readily formed are obtained (a) by the use of the free fatty acids; (b) by making the soap in the liquid. In the latter, the glycerin liberated by the saponification of the oil was not removed, and it therefore somewhat modified the appearance and consistency of the product.

A few experiments were also tried substituting potash for soda and ammonia, and it is interesting to note that with certain oils the products obtained are quite equal in

consistency to those obtained with the two former alkalis. Although lime and stearic acid gave an unsatisfactory result, further work with lime and the carbonate on the other fatty acids might yield better products. The results obtained with aqueous potash are summarised in the following table (IV.), but no experiments have as yet been carried out with dry potash, although it will be noticed that very different results are obtained when dry caustic soda is substituted for the lye.

TABLE IV.
EXPERIMENTS WITH AQUEOUS POTASH.

Stearic Acid.	Oleic Acid.	Olive Oil.	Cotton-Seed Oil.	Tallow.	Suet.	Castor Oil.
White pearly hard mass.	Cream coloured thin jelly.	Soft, cream coloured mass, some separation of paraffin.	Firm white flaky mass resembling lard.	Soft yellow soap separating from oil.	Soft flakes of soap, with considerable separation.	Firm white mass; no separation.

The procedure adopted to obtain these products varied somewhat with the particular experiment, but the following is a general outline of the method used in the laboratory:—100 cub. cms. (82.1 grms.) of commercial paraffin were heated in a capacious basin on a water-bath. The fatty acid or oil used was then added in proportions varying from 5 to 10 per cent. In the case of suet, 20 per cent. was necessary to obtain the best results. When the mixture was at a temperature of about 80° C., it was thoroughly agitated by means of a wheel egg whisk, and then from 1 to 2 grms. of dry soda or an equivalent amount of alkaline solution, &c., introduced. The agitation was then conducted rapidly for a few minutes, during which the saponification of the fat or neutralisation of the fatty acid takes place, and an emulsion of the melted soap with the paraffin is produced. In some cases the soap appears to be soluble in the paraffin at this temperature, but the mixture on cooling solidifies. In the best experiments the mixture gelatinises while still at 80° C., and it becomes difficult to rotate the agitator in the basin. It is obvious that the uses of a solid petroleum which was perfectly fluid at such a temperature would be somewhat limited, but it is more advantageous to determine the melting points of the solid products in the usual way than make any special determination of the temperature at which they become solid on cooling.

The melting points of the product depend on the kind of solidifying agent employed, some being viscous at the ordinary temperature and others varying from 42° C. to 132° C.

Among the vegetable oils employed, the best results were obtained with coconut oil and castor oil, both products being hard and white and far superior in these respects to those obtained when olive or linseed oil were used.

The apparent total separation of the resin soaps from paraffin is noteworthy, as it was hoped that the resin acids would form compounds which would gelatinise the petroleum in a similar way to the vegetable fatty acids. The hardness and consistency of these products varies directly with the amount of soap present, those containing the most soap being the hardest, and, as already alluded to, the presence of glycerin when the gelatinisation is effected by the saponification of an oil or fat tends to lower the consistency to that of a buttery mass. In the case of castor oil the presence of glycerin resulting from its saponification does not, however, prevent the product from being a solid. The products obtained when dry soda is used in the saponification are usually darker in colour, more translucent, and less firm than those made with aqueous soda. Nevertheless, a greater number of good products were obtained with dry soda than when an aqueous solution was used, as the latter class include examples which were absolute failures, the soap produced apparently having no power of occluding of mixing with the paraffin.

On reference to Table I., the influence of water on the combination of finished soap with paraffin will be observed. The product made in this way is substantially that covered by Smith and Pearson in their Eng. Pat. No. 3044, 1889. Desiccated soap refuses to unite with petroleum at the temperature obtained on the water-bath, but on the addition of a small quantity of water and continuing the agitation, a product was obtained which when cold formed one of the best, both from its degree of hardness and its permanency in the air. It would seem that water, or possibly glycerin, was necessary to ensure the formation of these products, and that the solidification was purely mechanical, the soap frothing with the water and then enclosing the paraffin along with or in place of the air in the small bubbles formed.

The failure of the elaidin and elaidates to unite with the petroleum was a disappointment, as I can find no reference to any previous experiment in this direction. Possibly some of the new methods, such as Schmidt's, for the conversion of oleic acid into iso-oleic and stearic acids might be worked to advantage in conjunction with a petroleum solidification process. At the same time it will be noted that several of the products obtained by solidifying with oleates were very satisfactory.

All these processes for the utilisation of various soaps in order to solidify petroleum, are probably covered by the existing patents, especially those of Lawson (Eng. Pat.

2971, 1888), and of Smith and Pearson already referred to. At the same time no one has drawn attention to the modifying action of the glycerin if allowed to be present in the finished product. Saponification by means of silicate of soda is covered by Lawson in his patent, but the use of sodium aluminate appears to be novel. Sodium aluminate appears to be superior to sodium silicate with many oils. It is a much more efficacious agent, for example, with both tallow and olive oil, as it renders these oils available for solidifying petroleum, and which could not be effected under the same conditions with water glass. A patent dating so far back as 1883 by S. M. Eiseman, (No. 3972) apparently covers all methods of making soaps in conjunction with paraffin, either by the action of alkali on fatty acids or on the unsaponified fats and oils. This patentee has also devised a method of protecting the granulated petroleum from atmospheric influences and the action of a moderate temperature, by coating the product with a mixture of calcium or magnesium salts and sodium silicate. He draws attention to the hardness of the products obtained with castor oil and thus confirms what one would conjecture from a knowledge of the soaps made therefrom.

Some interesting products can be obtained by the blending of a soap solidified petroleum with petroleum jelly. When equal quantities of vaseline and refined petroleum are heated together and 10 per cent. of oleic acid and the requisite quantity of dry soda added, a jelly-like and yellow product is obtained which resembles ordinary vaseline in appearance, but of softer consistency and smelling of petroleum. When stearic acid is substituted for the oleic acid a pale yellow translucent jelly is obtained with dry soda, and a pale yellow opaque jelly when aqueous soda is employed. These admixtures may probably be found useful as a lubricating medium and seem to indicate that useful products could be similarly made from a petroleum from which the lighter spirit only had been removed.

In Eiseman's patent already referred to, entitled "Improvements in heating volatile or inflammable fluids and oils for storage, transportation, and other purposes," an apparently essential part of the process consists in the admixture with the vegetable oil and paraffin before saponification of "an acid or acid combination." It is difficult, however, to see what part the acid plays in the process, as although he uses sulphuric acid and hydrochloric acid in many of the examples he cites, yet with castor oil no acid is employed, "owing to the peculiar acid found therein." As an alkali is subsequently added to bring about the saponification, I have made no experiments in this suggested variation. He further states that when a dry alkali is employed no heat is necessary, but when a lye is used it should be hot, but the temperature should be kept as low as possible. In the experiments done in my laboratory, heat has been found to accelerate if not absolutely to be necessary for the reaction when dry soda is employed, but in no case has the temperature been lower than that obtained on a water-bath. On the other hand, Smith and Pearson, who incorporate 3—5 per cent. of dry soap with the oil, recommend a temperature a little above 280° F. while the soap is added, and afterwards raise the temperature to 400° F. if necessary. At this high temperature the product is liquid and the process is necessarily complicated by the special closed apparatus required when a body like paraffin with volatile constituents is raised to such a temperature.

Lawson's patent and one by Stitt (No. 8604, 1888) are both for incorporating petroleum in soap so as to make an improved detergent, and are therefore somewhat foreign to this inquiry.

B.—Solidification with Vegetable Saponifiers.

Experiments have been tried with the bark of *Quillaja saponaria* which has long been known as producing a semi-solid mass when agitated with a mixture of oil and water. Saponin, the glucoside present in this bark, probably gives it this property, and as it is also contained in horse chestnuts, soap worts, and many plants of the *sapindaceae* and *minoseae*, it may be possible to substitute one or other of these for the *saponaria*.

The use of Quillaia bark has been covered by two patents (Grave, No. 13,673, 1888, and Stringfellow, No. 14,832, 1890), but in my experiments with it the products have not equalled in hardness nor consistency those obtained by the use of soap.

The best results obtained by its use are given below.

Experiments.	Results.
1. After Grave's process, using 10 per cent. of saponaria decoction.	A stiff pinkish opaque jelly.
2. After Stringfellow's patent, using 1 per cent. ground bark and afterwards adding 10 per cent. water.	A stiff white opaque jelly, which slowly yields its petroleum as a liquid.
3. The same, but using 5 per cent. of bark and the same quantity of water.	White opaque jelly, more permanent than No. 2.

The essential difference in these two methods of working is the substitution of the powdered bark and water for the decoction in the latter process. There is very little difference in the appearance of the product, but it is stated that it is more economical to use the powdered bark, although when its extraction is properly conducted, the whole of the saponin should be present in the decoction, and thus prevent any waste of the bark.

From the low price of saponaria bark at the present time and the small percentage required, it is probably one of the cheapest materials to use for solidifying oils for transport and storage.

C.—Solidification with other Reagents.

The similarity between the absorption of water and paraffin by soap naturally led one to experiment with other materials which form solid masses with water. Gelatin, glue, albumen, casein, gum, and many mineral substances suggest themselves, but on trying these bodies under different conditions no very satisfactory results were obtained.

1. *Gelatin*.—On melting from 3—8 per cent. of size with a small quantity of water on the water-bath, and adding the petroleum, after violent agitation and cooling the mixture solidifies to a tough jelly. With the smaller percentages of gelatin, it was easy to remove the oil mechanically retained by the jelly by squeezing, and on standing it slowly oozed away, and when the percentage of gelatin was as much as 8 per cent. the amount of water required for solution was sufficient to prevent the paraffin from burning. When bichromate was added to the gelatin mixture before cooling, the product also turned out unsatisfactory, and with tannic acid the product obtained was so brittle that it is difficult to see any use for such a material.

2. *Albumen* coagulated by warming and with acetic acid did not retain any petroleum.

3. *Milk*, milk extract, and casein likewise gave negative results.

4. *Ghatti gum* mucilage and ferric chloride give, as is well known, a thick gelatinous mass, but the formation of this compound in the presence of petroleum does not prevent the latter from being easily removed again from the mixture.

5. *Inorganic precipitation*, e.g., alum by ammonia, calcium chloride and borax, zinc sulphate and soda, calcium chloride and a sulphate, gave negative results.

The reliquefaction of these various products by means of heat or by appropriate reagents is a question of considerable practical importance. A ready means of solidifying petroleum for transport and subsequent reliquefaction for use would be a desideratum. Where saponaria bark is the agent employed, the solid can be reliquified by the addition of a small quantity of dilute acid, probably owing to the

decomposition of the glucose into its sugar and sapogenin. Stringfellow has claimed the use of acetic acid for this purpose, and recommends the use of 2½ per cent., which he pours over the surface of the jelly so as to entirely cover it. Mineral acids do not behave so well as acetic acid, although if the breaking up of the mass is due to the hydrolysis of the glucoside, dilute sulphuric acid would seem to be the most suitable. When a soap is employed, the oil can be reconverted into the liquid state by heat or by warming with a mineral acid. The completeness of the reliquefaction in the case of a soap-solidified petroleum obviously depends on the nature of the fatty acid liberated from the soap. As I have already mentioned, free stearic acid and water form a translucent jelly with petroleum, hence if a stearate soap has been used, a warm acid will be required, and the stearic acid liberated immediately removed from the warm oil if a liquid is again desired. With oleate soaps the same difficulty does not occur as oleic acid forms no solid product with petroleum.

The disadvantages of a solidified petroleum which is liquid at a temperature below 100° C. are obvious if the material is to be used for burning purposes or as a constituent of briquettes. Stringfellow's saponaria product is stated not to flow when burnt; but apparently his jelly is not primarily intended to be used as a fuel. Many of the soap-solidified products melt at a temperature below 100° C., and would be practically useless for such work. Probably a suitable material for a fuel could be obtained by incorporating the solidified petroleum with finely-divided porous mineral matter, such as kieselguhr or ground brick. Using the latter, I have found such a mixture to burn very well in the open air, and it might be advantageous to substitute such a lamp for outdoor illumination in place of the naphtha lamps at present employed. The Solid Petroleum Pioneer Company, recently formed to exploit a patent applied for by the Messrs. Clenhall, is apparently about to introduce such a mixture. It may, however, be interesting to mention in this connexion that one of the earlier patentees (Eisenman) has already suggested the use of solidified petroleum for incorporation with sawdust, coal, &c., in the making of fuel. In my earlier experiments, using ammonium stearate for the solidification of petroleum, an attempt was made to overcome the difficulties met with in Russia, where this stearate has been used for the manufacture of petroleum candles. Apart from the objectionable smell which such candles emit, the loss of weight owing to the evaporation of the paraffin is considerable. Although only 10 per cent. of stearate is suggested in Russia, my own experiments indicate that about 20 per cent. of stearic acid must be incorporated to obtain a product as firm as ordinary candle material. The loss on exposure to the air may be in part prevented by protecting the surface of the candle with a glaze of some organic material impervious to paraffin. When incorporated with coal-dust, the solidified petroleum, if used in large amounts, can replace pitch in a briquette and form a block fuel which readily ignites.

I have already drawn attention to the vaseline-like products and their possible utilisation as lubricants. Since putting these notes together, I note that another application for an improved process for solidifying petroleum has been patented by S. Lewes.

DISCUSSION.

MR. STRINGFELLOW said that he was the patentee of one of the processes referred to by the author. The object of that process was to deal with every kind of liquid hydrocarbon, and, in the case of petroleum, as it exuded from the well at the rate of, perhaps, 1,000 gals. per hour, so as to precipitate it rapidly into a gelatinous mass. For this purpose, the bark of the *Quillaia saponaria* was found to be readily applicable, all that was required being to pulverise the bark, and add it with a small proportion of water to the petroleum in cask. Upon agitation, the whole of the mixture solidified into a gelatinous mass in about two minutes, whether the oil thus treated was of a gravity of 0.650 or of the heaviest description, namely, what was known as dead oils—the refuse from the distillation of creosote.

Mr. Stringfellow asserted that in this condition petroleum could be used as fuel with very great advantage, or, on the other hand, it could be readily re-liquefied, in which case the water and bark would be precipitated, and the oil decanted off.

Mr. BOVERTON REDWOOD said that, after the very candid opening observations of Dr. Rideal and his too complimentary reference to himself, he felt a little diffidence in offering any critical remarks on the paper, especially as he was afraid that he would not be able to give any useful information. As the author had pointed out, the so-called solidification of petroleum—the conversion of mineral oils into a more or less solid substance—had been attempted many years ago; it certainly could not be less than 15 years since the possibility of so treating petroleum had been demonstrated by an enthusiastic inventor in his (Mr. Redwood's) own laboratory. It was not, however, only in relation to the incorporation of mineral oils with soaps intended for detergent purposes that the subject had made progress since that time; and he was bound to say that, in his opinion, the results given in the paper before them did not altogether satisfactorily indicate the advance which had been made. In some cases the experiments, the results of which were recorded, would, to his knowledge, have furnished different results had they been carried out under somewhat different conditions. Unfortunately, however, the work which had been done was, as the author had stated, of a private nature; and he (Mr. Redwood) was fearful that he might be led into saying things which ought not to be said if he entered into any critical discussion of the paper. The aims of the inventor in relation to the so-called solidification of petroleum might be divided under four heads: first, the production of a soap for detergent purposes; secondly, the manufacture of a grease for lubricating purposes; thirdly, the temporary solidification of petroleum with a view to its transport as a solid, and re-liquefaction; and, fourthly, the conversion of petroleum into a solid form available for use as fuel. The first of these aims was outside the scope of Dr. Rideal's paper, and he did not propose to say anything with reference to it. In respect to the second, the production of a lubricating grease, he presumed from his remarks that he (Dr. Rideal) was not aware that a material of that description, made by one of the processes referred to, had been an article of commerce for years past. A grease of that kind was found under certain conditions to give satisfactory results when employed for the lubrication of machinery. It was either applied through the medium of a spring grease cup, or its supply was regulated by the liquefying action of a copper rod resting on the bearings. It occasionally happened that the employment of such a lubricant resulted in heated bearings; it was therefore necessary for the engineer to carefully watch the action of the lubricators and be prepared to supplement the grease with a copious supply of oil in order to reduce the temperature. That was a serious objection; but it was one which might be overcome. It indicated, perhaps, that the grease in question was not sufficiently sensitive to alterations in temperature. With regard to the other two aims of the inventor, he gathered from the stress which the author had laid on the re-liquefaction of the petroleum, that he looked upon the solidification of the oil with a view to its transport as being more important than solidification in relation to the employment of the product as a solid fuel. He could not agree with that view. Taking for example that which of all petroleum products was the most important commercially, namely, kerosene, it was well known that a great portion of our supplies of that product were brought to the consuming markets in bulk; and practical experience showed that the transport of the liquid in the specially-constructed tank steamers now employed, resulted in a great saving of time and labour. The loading and discharging of an ordinary oil cargo, which formerly occupied a gang of men for many days, could now be effected by means of a steam pump in about as many hours. Obviously, therefore, it would be a retrograde step to convert such a material into a solid, and handle it like coal. At the same time, he considered that there might be certain cases of transport in which it would

be advantageous to have the petroleum in a solid form. In his opinion the most important branch of the subject was the use of the material as a fuel, and he was glad to be able to state that the difficulty which appeared to have been experienced in the production of a solid fuel which would burn without fusion, appeared to have been overcome. He had reason to believe that a material of that character would shortly be available; and, looking to the enormous extent to which petroleum was now used as liquid fuel, there could be little doubt that there must be an immense field for the employment of petroleum in a form in which it could be burned in an ordinary fireplace. He might add in conclusion, that, assuming that the special risk connected with the storage of petroleum lay in the liability of the substance to escape in a liquid form under the influence of fire, a solidified petroleum of a suitably high flashing point which did not fuse when burning might presumably be stored without exceptional risk.

Mr. D. A. SUTHERLAND: As Mr. Redwood had spoken exhaustively with reference to the use of solidified petroleum as a fuel, he only desired to make one remark with reference to his experience with the solidification of mineral lubricating oils. Since he first became acquainted with the reaction some eight years ago, he had from time to time solidified such oils and experimented with the view to finding out the chemical reaction that took place. He might at some future time bring forward the information which he had obtained. No doubt, as Dr. Rideal had said, the action was most mysterious. He understood him to say that such a reaction did not occur in the absence of water. His experiments were chiefly made with the lubricating oil obtained in the Scotch shale industry of a specific gravity of about 0.885, and he found it solidified with alcoholic soap solution or exsiccated soap. His object then was the manufacture of railway grease, and the substitution of vaseline in grease materials such as harness paste, for the solidified oil resembled vaseline in colour only and was seldom free from objectionable odour of mineral oil. It was of a jelly-like nature not being soft and pasty like vaseline. Thus, apart from objections from a medical point of view, it would not be a satisfactory substitute. After some time, he found that his compounds began to re-liquefy; but he had some with him which were made some five years ago, and while these, in some cases, had partially liquefied, in others they had remained much in the same condition as when they were made. In using dry soap he had found in all his experiments that it was advisable to use a temperature of about 400° F. The mixture of oil and soap was heated in an enamelled iron basin on a stove, and stirred with a glass rod, when the mixture instantaneously thickened; all that was necessary was then simply to pour the liquid jelly into bottles where it set in cooling. He also understood Dr. Rideal to say he had not found that any inorganic substance produced solidification. He might add that it was a well known fact to those experienced in the manufacture of mineral oils, that occasionally, for some mysterious reason, after treating with acid and alkali the oil becomes a complete jelly. As he hoped to deal specially with the subject later on, it was unnecessary to say more then, than to thank Dr. Rideal for giving them so complete a summary.

Mr. PETER McEWAN said he was under the impression that Dr. Rideal had said that aluminate of soda had never before been used for the purpose of gelatinising petroleum. In that, he thought, he was in error, for it was employed in the manufacture of several lubricating bodies, and was recommended for that purpose in Brandt's work on fats and oils. He thought, too, that an important factor had been omitted from the paper, inasmuch as no mention was made of the melting points of the various bodies which the author had produced. That was a very material point, and he hoped that Dr. Rideal would be able to supply the omission. He could not help thinking that the importance attached to the employment of solidified petroleum as a substitute for coal was somewhat amusing. Supposing petroleum could be got as low as 2d. per gallon, by the time it was solidified it would cost about 3d. per ton, and he

hardly thought that that was a price which would be tolerated even in London, where one was accustomed to pay a pretty high figure for fuel.

Dr. Rideal, in reply, said that it was hardly necessary for him to refer at any length to Mr. Stringfellow's remarks, as they dealt with his own process rather than with the paper before the meeting. Mr. Boyerton Redwood had characterised his paper as being not quite up to date, but he had not specified exactly in what particulars his paper was wanting. In the paper he said that for obvious reasons certain gentlemen had been reticent on the subject; and it was to be inferred from the character of Mr. Redwood's remarks that he wished to include himself amongst the number. At any rate, he was glad to find that the knowledge he possessed on the subject was as complete as that which Mr. Redwood was willing to communicate to the Society. With regard to the production of greasy bodies, he was aware that for lubricating purposes such a mixture as he had described was already in use. Some experiments had been specially directed to ascertaining the viscosity of such mixtures, but, as far as he knew, the actual composition of the grease in the market was not generally known, so that, perhaps, his remarks on that head properly came within the same category as his other statement. With regard to the question of transport, he quite agreed with Mr. Redwood that under most circumstances petroleum could be more advantageously carried in tank-steamers than as a solid, but in certain other cases the opposite would be the case. Especially would it be so in India, where large quantities of castor oil were obtainable cheaply, and could be utilised for solidifying the native petroleum, to which Mr. Redwood had himself drawn attention at a recent meeting of the Society. It seemed to him that it might be feasible to utilise both those bodies on the spot by making a solid fuel for use on the native railways, if not for export. Recent experience in Southern Russia had shown that there were disadvantages in using liquid petroleum for that purpose, so that solidified petroleum might give better results. He was glad to learn that a reliable solid fuel made from petroleum was likely to be introduced soon. Mr. Redwood had not told them how it was to be made, and probably it was one of the patents to which he (Dr. Rideal) had referred as not yet disclosed. With regard to Mr. Sutherland's remarks he did not know that he had anything to say in reply. He had mentioned the vaseline-like products in his paper, but the beeswax product had never been, so far as he knew, mentioned before. That might be said to be a vaseline-like product; and it had certain advantages over a viscid material made from ordinary soap. Mr. McEwan's remarks seemed to him to refer to a patent that Mr. Redwood had drawn his attention to by Marriott, in which a combination of the oils with aluminium salts, forming oleate and stearate of alumina, had been covered for this purpose. But as far as he knew, sodium aluminate had not been described before as being superior for forming these solid products. With reference to the melting points, he might say that they were given in the corrected proof of his paper, and that they varied with the melting points of the soaps or fats employed.

Manchester Section.

Chairman: Ivan Levinstein.

Vice-Chairman: Edw. Schunck.

Committee:

Hon. Local Secretary:

J. Carter Bell,

Bank House, The Cliff, Higher Broughton, Manchester.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held Friday, November 6th, 1891.

DR. EDW. SCHUNCK, F.R.S., IN THE CHAIR.

CHAIRMAN'S ADDRESS.

You will, I am sure, join with me in regretting the enforced absence on this occasion of our esteemed Chairman, Mr. Levinstein. Having been invited to take his place at this the first meeting of the session, and give a short opening address to the members of the Section, I do so with some reluctance, knowing how much more effectively, considering his intimate knowledge of what has recently been done and is being done relating to the various branches of chemical technology, our Chairman would have performed the duties devolving on me this evening.

To go over a wide field and into a variety of subjects on this occasion would not be possible within the time at my disposal, nor would it be desirable if possible. I shall confine myself, therefore, to some remarks on a few subjects of general interest.

There is no subject that has of late attracted more general attention, not on the part of experts only, but also on that of the general public, than that of technical education. It has been much discussed in various quarters and widely different views have been expressed in relation to it. Had our Chairman been present this evening he would probably have given us the benefit of his experience and information on this subject—a subject to which he has paid great attention. I must confine myself to a few general considerations.

An idea seems to prevail in some quarters that when once efficient technical schools have been established and are in operation, it will be possible to send a youth there, duly prepared or not, who when his course is completed will be able to take his place as an efficient workman or manager in any trade or branch of manufacture which he may have selected. That this is a complete delusion any one who has paid the least attention to the subject must see at once; for in the first place technical education is essentially and necessarily special education, and cannot advantageously begin before the general education is completed, *i.e.*, before some amount of general knowledge has been acquired, certainly not until a ready command of one language at least has been attained, for one who cannot speak and write correctly cannot for the most part think correctly. It may be said on the other hand that the boys who have completed their course at any of our first-class schools are duly prepared for a technical course; but if I understand the matter rightly, the proposed technical schools are not intended so much for the children of the higher classes, who can be sent regardless of expense to any one of the numerous excellent institutions already existing on the

Continent, but are intended rather for those of a somewhat lower class, the class from which the managers and foremen of our works are mostly taken. The question, it seems to me, is whether the children of members of this class have been and are properly prepared on leaving school to enter on the courses of instruction to be provided for them at the proposed technical institutions. Those who have read the interesting report lately presented to the council of this city by the members of the Technical Instruction Committee who were appointed to visit the educational institutions and schools on the Continent, as well as the report of a deputation from the Manchester Technical School, may possibly be led to think the establishment of technical schools on the model of those on the Continent no difficult task. No doubt it would be an easy matter for the government or municipalities of a wealthy country like ours to build large schools, to supply them with all necessary apparatus and appliances, to appoint competent teachers, and so on, but can they obtain the human material in the shape of scholars to fill these schools and work profitably in them? I confess I have my doubts in this respect. It must not be forgotten that as regards commercial and scientific education some of the continental nations are a generation or more in advance of us. A boy leaving a quite ordinary commercial, *i.e.*, non-classical, school in Germany or Switzerland has a perfect command of his own language, and has a sufficient knowledge of French and English to enable him to write and speak those languages fairly well. His general knowledge is on a par with this, and fits him for immediate entry into higher technical or other schools. Can we say the same of the pupils that have completed their course in schools of the same class in our own country? I am afraid not. In another respect, I fear, the expectations of the public, or a portion of the public, are raised too high. It is thought apparently that a boy, after passing through a technical school, will be able to enter at once on the practice of his own trade. This, however, can never be the case. Questions arise in practice for which no amount of systematic training can prepare the student. Some kind of apprenticeship must be gone through, whether called by that name or not. Difficulties, too, arise when working on a large scale which cannot be anticipated when operating on a small one, a fact which, in the chemical arts at least, is usually experienced by the student, however well trained, when proceeding from the laboratory to practical manufacturing.

On the whole I am inclined to think that the special industries for the promotion of which our Society was founded will not derive as much advantage from any system of technical education to be established in this country as some others, such as engineering and textile industries. Radical changes in great chemical manufactures, such as that of alkali, acids, bleaching powder, &c., occur but seldom, and when they do occur they have to be initiated by persons of profound chemical knowledge, such as is not likely to be possessed by anyone that has been trained in a technical school. When, on the other hand, new processes are firmly established, ordinary intelligence should be sufficient to keep them in good working order, and the same applies of course to such processes as have been going on almost unchanged for many years.

Of the manufacture of fine chemicals I know too little to pronounce any opinion, but I should imagine that the processes coming under this head must require the constant supervision of an educated chemist. There is, however, one department of industry in which even a moderate knowledge of chemistry may be of considerable use—I mean that of dyeing. It is no doubt a difficult task, taking an entirely new natural dyestuff, to separate in a state of purity and examine the colouring matter or matters to which its efficacy is due, and quite as difficult to discover a new artificial dyestuff which shall in any way surpass those previously in use; these are tasks which only an accomplished chemist is equal to. But to take in hand a new dyeing material, to ascertain its chemical and physical properties in general, to find out the various colours and shades it is capable of yielding with various mordants or without mordant on various fabrics, and, generally speaking, to what purposes it may be practically applied, should be quite within the competence of one who has passed through

one of the existing excellent dyeing schools, such as those of Manchester or Leeds, or any similar school still to be established. How much remains to be done by the technologist in this department of industry will be apparent to anyone on perusal of Mr. Thomas Wardle's very interesting paper on Tassar Silk read before the Society of Arts on May 14th last. Speaking of the various Indian dyestuffs, of which he used no less than 181 kinds in his experiments, Mr. Wardle says that he succeeded with them in obtaining results absolutely impossible with most of the artificial dyes, good as some of them are, and further that European dyers are unaware of the excellence of scores of to them unknown Indian dyes. I will not here enter on a discussion of the relative value of natural and artificial colouring matters; but I concur with Mr. Wardle that it would be of importance to acquire a knowledge of all the dyestuffs which nature presents for our use. It is possible that we have gone too far in our preference of artificial over natural dyes, and that some of the latter present advantages not attainable by the use of artificial products.

The few remarks I have made are not intended to disparage or discourage the attempts that are being made to improve our present methods of technical instruction, but simply as a warning to those, if any such there be, who think that the task will be an easy one and one that will lead to immediate and striking results.

There is another subject which has of late attracted much attention and to which a few words may on this occasion be devoted. I mean the state of our atmosphere and the state of our rivers as affected by the vast population here gathered together, and the various industrial and other pursuits carried on in our neighbourhood. To most people our fog and smoke laden atmosphere and our polluted streams are exceedingly disagreeable, perhaps even offensive. No doubt it would be very pleasant, probably conducive to health, if our atmosphere could be rendered as clear and pure as that of the Alps or the moors of Scotland. No doubt it would be pleasant if our streams were made clear, pellucid, sparkling, and the abode of numerous fish, so that the contemplative angler might repair to the banks of the Irk or Irwell and pursue his favourite pastime at ease. No doubt, too, though such a desirable consummation might not be entirely reached, it would be possible to make a near approach thereto, and render town life almost as healthy and pleasant as country life. The question is whether the advantages to public health and pleasant living would be commensurate with the enormous expenditure involved in such transformations. At a time when the indebtedness of our towns is on the increase, when our capitalists and manufacturers are being harassed, on the one hand by the exorbitant demands of workmen and on the other hand by the increasingly hostile character of foreign tariffs, it is a question whether it is wise and politic to increase taxation or lay on fresh burdens except for purposes absolutely required by the public welfare. The insalubrity of our towns, as caused wholly or in part by the state of our atmosphere and our rivers, must be proved before we can accept it as a fact. The argument as ordinarily stated, though not perhaps in these exact words, is somewhat as follows:—Our towns are unhealthy—everything that is unpleasant to the senses is unhealthy—the impure state of our atmosphere and our rivers is unpleasant to the senses, and therefore it is one of the causes of the unhealthiness of our towns. This conclusion may be or it may not be correct. Were this Section a debating society, which fortunately it is not, the following thesis might perhaps be set up:—The ordinary impurities of our town atmosphere and of many of our rivers are not prejudicial to animal and vegetable life, provided they do not exceed a certain amount, but on the contrary are rather beneficial. Were animal and vegetable pathology exact sciences like astronomy or physics, founded on systematic observation and experiment, the opinion pronounced in this thesis would ere this have been established as correct or it would have been proved to be inexact. What I maintain is, that we are not in possession of a sufficient number of facts to justify a certain conclusion one way or the other. We must not forget that the difference in effect of surroundings on animal and vegetable life is a result quite as much of a difference of degree as of

kind. What is beneficial in small quantities may be injurious on a large scale. For instance, oxygen, in the proportion existing in the atmosphere, is necessary for the maintenance of animal life, but pure oxygen is a poison. Carbonic acid again, as everyone knows, serves as a food for plants, but a plant immersed in pure carbonic acid gas is soon asphyxiated and perishes. Iron in small quantities is absolutely essential to the life of plants, but a large dose of an iron salt kills them at once. It is possible, therefore, that some of the ordinary impurities of town air may not be so injurious to animals and plants, provided it does not exceed a certain amount, as is commonly supposed. Large quantities of sulphurous acid, as is well known, affect plants prejudicially, but a small quantity may serve to bind the ammonia of the atmosphere and thus act as a fertiliser. Even the finely-divided carbon, the result of the imperfect combustion of coal, may serve a useful purpose. I have observed during a course of years a gradual diminution of insect pests in my garden, especially caterpillars, some kinds of which have nearly disappeared, and also of aphides. This I attribute to a thin coating of carbonaceous matter from the smoke of the adjacent town covering the leaves and other parts of plants so as to render them unpalatable to insect parasites without injuring the plants themselves. I do not attach much importance to the observation, which is not one of a scientific character, but I think the point worth attending to. Our concern at present, however, is chiefly with the effect produced by our vitiated atmosphere on the animal frame. No one need be told that our air is impure—the question is, how much of each impurity is present. Dr. Bailey is at present engaged in solving this question, so far as regards the air of Manchester. When his labours are completed we shall be able to say how much carbonic acid over and above the normal quantity, how much sulphurous acid, how much unburnt carbon, and other products are contained in a certain volume of the air of the town. In possession of these data the physiologist might take up the question and experiment on animals, confining them in artificial atmospheres into which certain amounts of each of the supposed noxious constituents should be introduced, and then ascertaining the effects produced on the health of the animals. This would probably be a somewhat difficult and laborious investigation, but when completed the results would afford a secure basis on which to found argument as well as legislation. No objection to such experiments on the part of anti-vivisectionists or other well-intentioned persons need be apprehended, seeing that the conditions to which animals would be subjected in such experiments would not be more adverse to health than those by which the human inhabitants of towns are for the most part surrounded.

The time at my disposal will not permit my entering on the cognate subject of the pollution of rivers and streams. This subject, a most important one as regards our district, is moreover being taken up and worked out by heads and hands so much abler than my own, I may be excused saying anything about it on the present occasion.

RESEARCHES ON THE FORMATION OF PIGMENT LAKES.

BY CARL OTTO WEBER, PH.D., F.R.S.

THE name "pigment lake" is applied to a class of pigment colours which, with regard to their chemical constitution, may be defined as insoluble salts of an organic colouring base or colour acid with either an organic or inorganic acid, or an organic or inorganic base. This definition applies to all true lakes, whatever be the medium, if any, they are fixed upon. A number of organic colouring matters, particularly the basic coal-tar colours, are capable of fixing themselves upon indifferent organic or inorganic media, such as starch, cellulose, alumina, China clay, and others, forming with them pigments, which at first sight appear

to be true lake pigments. But in most cases, on treatment with water, they lose more or less of the colouring matter, and are without exception extremely fugitive. The formation of the lake pigments as such is in every respect identical with their production upon the animal or vegetable fibre in the dyeing and printing industries, and we may say that dyeing and printing are only special cases of the production of lake pigments. In all those cases where the production of what I may term the free lakes differs materially from the application of the dyes in those industries, the difference is solely caused by the nature of the respective media upon which the colours or lakes are fixed.

Chemically pure lakes, that is, lakes the formation of which, according to their composition, can be expressed by a simple chemical equation, are manufactured in very moderate quantities only. They are used on a limited scale in calico printing, in the printing of window blinds and playing cards, and in leather dyeing. By far the greatest part of the lakes, which are manufactured at present on a most extensive scale, contain about 90 per cent. or more of various organic and inorganic and mostly white bodies. These are not unfrequently alluded to as diluents, or even adulterants; a very mistaken notion. On the contrary, I venture to say that whenever such bodies are used they are absolutely required, as they have great influence not only on the depth of shade but also on the characteristic appearance of the lake. This fact, however, more closely viewed, is found to be simply an extension of the well-known fact that one and the same dye, if applied to cotton, wool, and silk, produces in many cases strikingly different results. We find, therefore, that in the manufacture of lake pigments the composition and quantity of the body is quite as important as the method employed for the precipitation of the colouring matter upon that body.

According to our definition of a lake pigment as a salt, it is obvious that an organic colouring matter to be capable of forming a lake must be either a base or an acid. This explains why indigo, which possesses neither of these qualities, is quite incapable of forming lakes, and the unique method by which indigo is applied to the fibre is another illustration of this fact. We may therefore divide the organic colouring matters, according to their lake-forming qualities, into two large classes, basic and acid colouring matters, to which correspond fundamentally different methods of producing lakes.

(a.)—Lakes from Basic Colouring Matters.

All basic colouring matters contain in their molecule one or more amido groups or substituted amido groups, and at least theoretically, each of these groups is capable of combination with acids. Natural basic colouring matters are not known, but amongst the coal-tar colours a considerable number of basic colours have been produced. As a class they are distinguished by a dazzling brilliancy of shade and very great tinctorial power. As regards their fastness, with a few exceptions, they do not occupy a very high position, and on the average are in this respect inferior to the acid colouring matters. For all those purposes, therefore, where great fastness is sought after, the last-named class of colours will be more satisfactory.

The production of lakes from basic colours consists in the formation of insoluble salts by decomposition of the soluble colour salts by suitable acids or their salts. These need not necessarily be soluble in water. In the manufacture of free lakes this process of transforming the soluble colour salts into insoluble compounds is called precipitation. The most important precipitant of the basic colouring matters is tannic acid, which for the application of these colours to cotton is nearly without a rival. For the production of free lakes, however, the use of tannic acid has been nearly abandoned. This fact may partly be accounted for by the exceeding sensitiveness of tannic acid, and therefore also of its lakes, to the presence of iron, which in the practical manufacture of lake pigments is very difficult to avoid. But on the other hand, I have come to the conclusion that to a still greater extent this disuse of tannic acid is due to the crude rule-of-thumb way with which this precipitant has been used, and indeed is still

used. The principles of the production of lakes from basic colouring matters and tannic acid, the chemical proportions in which the reaction proceeds, and particularly the nature of the compound lakes of tannic acid and antimony, which are of such great importance in dyeing and printing, have never been so fully investigated as to allow of their successful application to the manufacture of free lakes. As a consequence of this the manufacturers have adopted methods for the production of lakes from basic colours which do not entail the difficulties and impediments of the tannic acid process, but which, unfortunately, entirely sacrifice fastness to brilliancy. The experience made in dyeing and printing has proved conclusively that the tannic-acid lakes are the fastest lakes that can be produced with basic colours.

Where the lake manufacturer uses tannic acid as a precipitant, his method of procedure is as simple as it is objectionable. He contents himself by adding the solution of colouring matter to the white body, which has been previously suspended in water, and he then adds a solution of tannic acid until the colour appears to be completely fixed upon the body. As soon as this point has been arrived at, the lake so obtained is washed and finished in the usual way, either as a lake in paste or in powder, which is more a question of the body the lake contains as of anything else. That this primitive method has been nearly abandoned at the present time is scarcely to be wondered at. In the first place, working according to this method, it is impossible to obtain anything like complete precipitation, except in case the colouring matter be the acetate of a colour base, which applies only to a certain brand of magenta; whereas all other basic colours are either hydrochlorides, sulphates, oxalates, or nitrates. If such a colouring matter is precipitated with tannic acid, the acid which is originally combined with the colouring matter is set free and at once begins to act upon the precipitated lake by redissolving part of it. How much, depends chiefly upon the nature of the liberated acid and the concentration of the solutions used. Acetic acid, in such concentrations as ever occurs in the manufacture of lakes, is incapable of dissolving them, and this is the reason why the acetates of colour bases are completely precipitated by tannic acid. But, as already stated, only a special brand of magenta is sold in the form of an acetate; all crystallised magentas are hydrochlorides, and so are the majority of basic colouring matters.

This impossibility to completely precipitate the basic colours with tannic acid is the cause of a considerable waste of colouring matter if lakes are prepared in the way described above. But worse than this is the fugitiveness and comparative dullness of these lakes. There is of course no difficulty in preventing this detrimental action of the acids liberated on precipitation with tannic acid, by simply performing the precipitation either in the presence of weak bases or carbonates, or in the presence of an excess of acetate of soda, or by precipitating with tannate of soda instead of free tannic acid. Whichever way we choose we always obtain complete precipitation.

By precipitating basic colours with tannic acid in the presence of weak bases, such as hydrate of alumina, fairly good results are obtained as regards brightness of shade. Instead of alumina, the carbonates of calcium and barium may be used, but as a rule the shades are inferior to those obtained in the presence of alumina, particularly so with magenta or methyl-violet; and there is no doubt that this is due to the detrimental action of lime or barium salts upon the lakes of the basic colouring matters. Tannate of soda is an excellent precipitant for basic colours, but the shade of the lakes so obtained is exceedingly dull and lifeless. If a lake so prepared is filtered and washed with hot water this fault still increases, and on addition of a few drops of acetic acid nearly the whole of the lake is dissolved. Undoubtedly the best results are obtained by precipitating the basic colours with free tannic acid in the presence of an excess of acetate of soda. The lakes are very bright, which to a certain degree is due to the liberation of a small quantity of acetic acid, and it is well known that in dyeing basic colours on cotton in most cases greater evenness and brightness are obtained by employing a faintly acid dye-bath.

In precipitating a basic colour with tannic acid we evidently transform it into a tannate, eliminating thereby the acid with which the colour base has been originally combined. The first question is now naturally as to the respective quantities of tannic acid and colouring matter, or rather the number of molecules of each which enter into reaction. This is a most important question, not only as regards the manufacture of lakes, but still more so as regards the application of basic colours and tannic acid in dyeing and printing. The reaction between the substances in question is a chemical one, and therefore one in which an absolutely fixed and invariable number of molecules take part. Many attempts have been made to solve this question, but although on the basis of practical experiments valuable information has been gained as to the quantities of tannic acid to be used for some of the most important colouring matters, the respective figures are at most not more than approximations, and do not in any way reveal the quantitative relations of the reaction. Theoretically we might conclude that one molecule of the monovalent tannic acid is required for each amido group contained in the molecule of any basic colouring matter. According to this 1 mol. of rosaniline would require 3 mols. of tannic acid. But on the other hand we know that the tri-acid salts of rosaniline are practically colourless, and cannot be dissolved in water without decomposing at once into free acid, and the mon-acid colour salt known as magenta. This might lead us to suppose that the tannic acid in forming a lake with a basic colour simply takes the place of the acid the basic colour is originally combined with. In this case 1 mol. of magenta would require only 1 mol. of tannic acid, but we find that following this rule Bismarck-brown would demand 4 mols. of tannic acid. The difficulty still increases if we try to apply this idea to the Benzaldehyde greens. The hydrochloride of this green corresponds to the formula:—

one molecule of it accordingly would combine with one molecule of tannic acid. The oxalate of the same green shows the composition—

which would indicate that at least two molecules of tannic acid are necessary to saturate one molecule of the green. The only conclusion these few examples lead to is that no amount of theoretical reasoning will ever enable us to determine the amount of tannic acid required by each of the many basic colours. It also must not be forgotten that the basic dyes of the trade may only in a very few instances be considered as practically pure substances. Most of them contain from 5 to 75 per cent. of indifferent soluble matter, such as dextrin, sugar, common salt, Glauber's salt, or sodium carbonate. Only those colours which are sold in the form of crystals may for all practical purposes be considered as pure. Supposing, therefore, the molecular relations between any basic dye and tannic acid to be known, in the majority of cases we should still require to estimate the amount of

pure colouring matter contained in a given sample. This is a task which at present is considered to be one of the most tedious and difficult to be met with in analytical chemistry.

In view of all these difficulties the way to solve the problem in question in a practical manner might appear to be the analytical estimation of the quantity of tannic acid necessary for the complete precipitation of a definite quantity of basic colouring matter. This is actually what the manufacturer does on a large scale, if he adds to the solution of colouring matter and suspended mineral body, a solution of tannic acid, until the precipitation appears to be complete. He simply aims at a certain physical condition; of the chemical reaction in this process he knows nothing. This slipshod way of working is directly responsible for the very bad reputation the lakes from basic colours enjoy. Working under these conditions the lakes will contain at the utmost only a fraction of that quantity of tannic acid which would have been required for the thorough fixing of the dye. The greater part of the latter is simply mechanically attached, partly by the body of the lake, partly by the real tannin lake which has been precipitated. All this mechanically fixed colouring matter is utterly incapable of resisting the action of the light and air, and a few hours' exposure of such a lake to direct sunlight is often sufficient to destroy its beauty beyond recall.

In my opening remarks I have been referring to the well-known fact that indifferent organic or inorganic bodies are able to fix upon themselves large quantities of basic colouring matters. The real cause of this phenomenon has never been clearly established, but in the meantime it has been christened "molecular surface attraction." Great quantities of lakes are produced in this way, containing nothing but the colouring matter and the base or body, generally starch, hydrate of alumina, or China clay. The distinguishing feature of these lakes, which with the genuine article have nothing in common but the name, is their extraordinary fugitiveness. Tannin lakes, however, are to a much greater extent than even the above-named bodies capable of mechanically fixing basic colours. Accordingly, in producing a tannin lake as just described, a certain quantity of the colouring matter is in the first instance taken up by the body before any tannin is added at all, and subsequently each drop of the tannin solution on being added carries down about twice as much colouring matter as is required for the formation of the normal lake. A simple calculation will show that even under the most favourable circumstances no more than about half the colouring matter contained in the lake is there fixed as a true tannin lake, the rest being present in the free state. Washing with water will only remove a small quantity of this free colouring matter, but it is worth mentioning that such washing is always most injurious to the brilliancy of the lake. Lakes made from magenta, methyl-violet, and Benzaldehyde green behave so in a remarkable degree.

The quantity of colouring matter absorbed by the above-mentioned bodies depends very much upon the nature of the body and its state of subdivision. But on the other hand the nature of the colouring matter is also of great influence, and it appears that the strongest colour base shows a minimum and the weakest a maximum, of mechanical fixation. Of perhaps as great importance is the observation I made that also the nature of the acid which combined with the colour base forms the commercial dye, has a most decided effect upon the phenomenon in question, the strongest acid corresponding to a minimum, the weakest acid to a maximum of so-called surface attraction. These observations may be briefly expressed by saying that the amount of surface attraction is inversely proportional to the respective strengths of the various colour bases and to the respective strengths of the acids which are in combination with them.

These relations are clearly expressed in the experiments registered above. The figures were obtained by suspending 2 grms. of alumina in the form of aluminium hydrate in 50 c.c. of water, and adding so much of a half per cent. solution of colouring matter that a drop of the mixture just began to show on filter-paper the first trace of unabsorbed, i.e., running colouring matter.

100 Parts of Al_2O_3 absorb

Colouring Matter.	Parts.	Manufacturer.
Bismarck brown G	8.30	Hampson Bros., Manchester.
Acetate of Magenta.....	7.13	Dan. Dawson Bros., Limited, Huddersfield.
Methyl violet B, extra ..	4.87	Bad. Anilin und Soda fabrik.
Brilliant green, cryst....	3.85	Küchler und Buff, Crefeld.
Magenta, large cryst.	3.53	Dan. Dawson Bros., Limited, Huddersfield.
Indazine M.....	1.96	L. Cassella & Co., Frankfort-on-the-Maine.
Methylene blue B, concr.	1.62	Meister, Lucius, and Brünig, Höchst.
Thioflavine T.....	1.43	L. Cassella & Co., Frankfort-on-the-Maine.
Solid green, cryst.....	1.21	Küchler und Buff, Crefeld.
Safranin G G S.....	0.83	L. Cassella & Co., Frankfort-on-the-Maine.

These remarkable relations between the absorption of colouring matters and the strength of their respective colour bases and of the acids combined with them, show that this surface attraction in all its details is perfectly identical with the well-studied phenomenon of dissociation, which occupies such an important position in the theory of mordanting with the salts of antimony, tin, iron, chromium, alumina, and others. All these salts are more or less capable to dissociate according to the strength of the respective bases and the acids these are combined with, exactly as we found for the basic colours.

This description of surface attraction as dissociation seems, however, incompatible with the fact that the colour bases of most basic colours are colourless, or nearly so, while those lakes formed through surface attraction are nearly all fairly strong in colour, which ought not to be the case if dissociation had taken place resulting in the fixation of the insoluble colourless base of the colouring matter upon the indifferent body present, whereas the acid of the colouring matter would be free in solution. But this objection carries very little weight with it, as it is highly improbable for such a dissociation to result in a quantitative separation of colour base and acid, and the very fact of these dissociation-lakes still being coloured products only proves that the dissociation of the basic colouring matters proceeds on the same lines as that of the above-mentioned inorganic salts, namely, in the production of basic salts insoluble in water.

The capability of basic colouring matters to form basic salts is undisputed, and it is also well known that the latter are either totally insoluble in water or soluble with great difficulty, but all these basic salts are of a very strong colour. These circumstances can easily be demonstrated by adding to a moderately strong solution of Benzaldehyde green a concentrated solution of Glauber's salt or acetate of soda, when a basic salt is precipitated in the form of a dark blue green resinous mass, which in water free from carbonic acid is nearly insoluble. Of course this dissociation must be accompanied by a loss of colouring power, and it is not at all difficult to show that the lakes produced under that influence contain the colouring matter in what I might term a weakened and generally altered form. If we produce such a dissociation-lake upon a body of China clay we invariably find the shade to differ, frequently in a very considerable degree, from the shade of the corresponding tannin lake. As a rule the red dissociation lakes are yellowish, the violet and blue ones redder, and the green ones bluer. If we add to any such lake tannic acid or any other preferably organic acid, a considerable change takes place, and the colour of the lake develops immediately into a new, often more than 50 per cent. stronger shade, thus proving that indeed the lake in its first stage contained the colouring matter in a dissociated and therefore partly colourless form. As a more striking illustration in proof of the dissociation we may wash one of these lakes with a large quantity of boiling water. Only traces of colouring

matter are found to go into solution, although at last the lake becomes practically colourless. If we now suspend this lake, which seems to have lost as nearly as possible the whole of its colouring matter, in water, and then add some tannic acid, the colour reappears in nearly its original strength. After this I think we may consider the dissociation of basic colours in the presence of organic or inorganic indifferent bodies to be an established fact.

That tannin lakes themselves are capable of absorbing in this way much larger quantities of basic colours than even the above-mentioned bodies, which are used to precipitate the lakes upon, has been already stated. I made this observation in attempting to estimate the quantity of tannic acid required to form lakes with the various basic colours, by titrating the latter dissolved in a 10 per cent. solution of sodium acetate with a 5 per cent. solution of tannic acid, until a drop of the titrated solution placed on filter-paper showed all the colouring matter to be completely precipitated. The results of these experiments are recorded in the following table:—

Colouring Matter.	Tannic Acid actually required.	Tannic Acid found by Titration.
Magenta	622	173
Methyl violet	510	138
Solid green	1,324	156
Methylene blue.....	620	198
Auramine.....	480	209
Chrysoidine.....	322	194

You see that on the average for the precipitation of the basic colours about half a molecule of tannic acid per molecule of colouring matter is sufficient. Now, on weighty theoretical grounds we know that at least one molecule of tannic acid is required to form a true lake, so that in those lakes at least one half of the colouring matter existed in free state. This shows that whenever tannic acid is added to a solution of any basic colour, complete precipitation of the latter is obtained with only partial conversion of the basic colour into a normal lake, and until a certain definite quantity of tannic acid is added over and above that quantity required for the physically complete precipitation of the basic colour, the lake obtained readily succumbs to the detrimental influence of light and air as well as soap and water. I need scarcely say that the same conclusions obtain in the case of cotton, mordanted with tannic acid and dyed in the presence of an excess of colouring matter; the attainment of which at present with the dyer is simply a question of good luck.

These difficulties are attributable partly to the fact that neither the dyer nor the lake manufacturer acknowledge the existence of definite molecular relations between colouring matters and mordants in any but the crudest form, and the calico-printer is in this respect no doubt considerably ahead of them. But on the other hand it must also be admitted that at least in the case of the lakes from basic colours our theoretical knowledge is, for reasons sufficiently stated, rather defective. We know that the formation of a lake from a basic colour and tannic acid is the formation of a tannin salt of the respective colour bases, and we know that at least one molecule of tannic acid is required for one molecule of the colouring matter, but beyond that we are treading on rather unsafe ground, and we must admit, if only the possibility, that two, three, or in certain cases even four molecules of tannic acid may be necessary. A reliable method for the estimation of the quantities of tannic acid actually combining with the various basic colouring matters is therefore of very great importance.

After the experience made in titrating solutions of basic colours with tannic acid, it is obvious that only by adding exactly the required quantity of the latter, or an excess of it to the colour solution, can we expect the whole of the colouring matter present to be converted into the normal

lake. What this exact quantity amounts to we do not know, but we are always able to use an excess, and we are also able to estimate volumetrically that quantity of it which did not enter into combination with the colouring matter.

For carrying out this estimation I use (1) a solution of 50 grms. of purest tannic acid and 200 grms. of chemically pure* sodium acetate in 1,000 cc. of distilled water; † (2), a solution of 1 gm. of permanganate in 1,000 cc. of water; (3), a solution of 5 grms. of dry indigo carmine and 100 cc. of pure concentrated sulphuric acid in 1,000 cc. of water. Of the basic colouring matters 1 gm. is dissolved in 200 cc. of water. The first operation is to determine the standard of the permanganate solution against the tannic acid solution. For this purpose 20 cc. of the latter are diluted to 200 cc.; 5 cc. of this diluted solution, 20 cc. of the indigo solution, and 750 cc. of water are mixed in a beaker and then titrated by slowly dropping in the permanganate until the well-known change of colour appears. In exactly the same way the indigo solution is titrated, and we are then able to calculate the number of milligrammes of tannic acid equal to 1 cc. of the permanganate solution.

The mode of procedure is now the following:—25 cc. of the colour solution are run into 20 cc. of the tannin solution, which is contained in a 200 cc. flask. The contents of the flask are gently agitated by shaking, and the flask put on a water-bath for 10 minutes; the colouring matter is now completely converted into the tannin lake. The flask is filled up to 200 cc., well shaken, and the 200 cc., or part thereof, is filtered into a dry flask through a dry filtered filter. 5 cc. of the filtrate, 20 cc. of the indigo solution, and 750 cc. of water are then titrated with the permanganate as usual. We find then the quantity of tannic acid required for 1 gm. of the basic colour under examination by a simple calculation, which leads to the general formula:—

$$\gamma = 0.32 b (a - c).$$

The number of cc. of permanganate used in the two titrations are respectively a and c in this formula; b stands for the number of milligrammes of tannic acid corresponding to 1 cc. of the permanganate solution.

Supposing we have found of the tannin solution as diluted for standardising 5 cc. + 20 cc. of indigo solution to require 35.4 cc. of permanganate, likewise of the filtrate from the lake 5 cc. + 20 cc. of indigo solution to require 33.2 cc. of permanganate; lastly, 1 cc. of permanganate to represent 1.420 mgrm. of tannic acid, then we have in the above equation $a = 35.4$, $c = 33.2$, $b = 1.42$.

$$\gamma = 0.32 b (a - c) = 0.32 \times 1.42 \times 2.2 = 0.9988$$

This would mean that 1 gm. of the examined colouring matter, to be completely converted in a tannic lake, requires 0.9988 gm. of tannic acid. From this we can easily find the molecular relations between these two, which figure, however, for practical purposes is of little value, as most of the commercial basic colours are very far from pure, containing as they do varying quantities of sugar, dextrin, or other suitable diluents. Only those colours which are sold in crystals may for practical purposes be considered to be pure.

In the table on the next page I have embodied the results of the examination in the described manner of practically all basic colouring matters known at present.

The first conclusion these results enable us to draw is that, with the exception of chrysoidine, the molecules of all basic colours require more than one molecule of tannic acid to form a tannin lake. This result is perhaps not particularly surprising as far as such colouring matters are concerned, which contain in the molecule two or more molecules of hydrochloric acid (Solid green, Bismarck brown, Indazine), but it is scarcely to be expected for those dyes, which although containing polyacid bases, still are only capable of forming colour salts with one molecule of hydrochloric acid, as is the case with the majority of basic colouring matters. With the exception of auramine and chrysoidine, all basic colouring matters appear to require for each molecule of colour base two molecules of tannic

* Must remain unaffected by permanganate.

† Addition of a trace of thymol acts as an excellent preservative.

Oxide, (1) C. Sulfate, (2) C. For 1 mol. of the colour base this amounts to: 652 = 2 mol. (1) Supposing it to be 75 per cent. strong, (2) 18 is about 50 per cent. strong, (3) 18 is about 50 per cent. strong, (4) A very strong safranine, nearly pure, (5) Those coloring matters appear to be about 50 per cent. strong, the red shades Muscarine I.R. and Basle blue R are obviously much stronger, (6) This figure for Verdine is unaccountably high, (7) This Chrysoidine is nearly chemically pure, (8) Appears to be about 50 per cent. strong, (9) Contains two molecules of colour base.

acid. The exceptional behaviour of auramine and chrysoidine, I have not been able to find a reason. Both are the mono-acid salts of di-acid bases, their respective formula being

for chrysoidine, and

for auramine. Considering the mono-basic nature of tannic acid, the 1.5 molecules of it combining with 1 molecule of auramine are rather difficult to account for. Of course, we can only speak of half a molecule of tannic acid as an expression of the simplest quantitative relations observed; actually it means that three molecules of tannic acid combine with two molecules of auramine.

The figures of this table and the previous one show that, generally speaking, one quarter the quantity of tannic acid necessary for the complete conversion of the basic colours

into a tannin lake, suffices to produce perfect physical precipitation. The danger involved in this fact I have already taken occasion to emphasise, and although the lake manufacturer is by far the greatest sinner, still I must say that not a single sample of cotton yarns did I find dyed with basic colours on a tannin mordant, which did not contain an excess of colouring matter, although perhaps, in fairness to the respective dyers, I ought to state that I only examined medium and dark shades.

On the head of the results gained, it is now easy to understand why tannate of soda, although a good precipitant for basic colours, gives very bad results both as regards beauty of shade and fastness. The majority of basic colours containing only one molecule of hydrochloric acid or its equivalent, can assimilate from the tannate of soda only one molecule of tannic acid, for reasons which are sufficiently clear, whereas two molecules of it would be required to fully develop the shade and produce the maximum of fastness. This fault of the tannate of soda can now be easily remedied by substituting for it what I might term the bitannate of soda. In using the latter we are indeed able to produce lakes which in fastness and beauty are most satisfactory.

It is noteworthy that Knechtlin, experimenting on the same subject, but on entirely different lines, obtained results

which approach my figures very closely, although they are still too low. Koechlin recommended the precipitation of the basic colours with such an acid tannate, and gives the following proportions:—

Magenta.—Four of colouring matter, 5 tannic acid, 2 soda crystals.

Methyl violet and *Solid green*.—Four of colouring matter, 5 tannic acid, 1 soda crystals.

The manufacture of tannin lakes has been nearly abandoned by the lake manufacturers, as the bad methods employed produced most ungratifying results, *i.e.*, dull and fugitive shades. Where the use of basic colours cannot be avoided, they are now almost exclusively fixed as arsenites, phosphates, or stearates, and palmitates, the two last ones by precipitation with soaps. All these precipitants give no fast lakes, but more or less brilliant shades, which to no small degree is due to the fact that the lake manufacturer, unconscious to himself, always uses these mordants in quantities amply sufficient for the complete fixation of the basic colours employed, a chance which he has never given to the tannin lakes.

In dyeing and printing, however, the use of tannic acid is predominant, and though other mordants are used sometimes, they are of subordinate importance. The dyer and printer knows well enough, that to produce darker shades stronger mordanting is essential, but dyeing according to molecular proportions is still a thing of the future. It is therefore not surprising to find that all the darker shades especially are more or less overdyed, and therefore more or less deficient in fastness to light, air and soap.

The results recorded in the tables above, and the analytical method brought before you, now enable the dyer to exactly estimate the quantity of basic dye that can be applied to a certain percentage of tannin mordant on the fibre. Of course, I am quite aware of the difficulty that the dyer uses a great variety of tanning materials besides tannic acid. The next thing required is therefore to extend the above tables for all these tanning materials, and also to estimate the quantities of the respective tannic acids which are fixed upon cotton on treating it in the various tannin baths of different strength. This involves some work, but there is no practical difficulty in the way of doing it.

It has been known for a long time to the dyer that the beauty of tannin lakes, as well as their fastness to all influences, is considerably enhanced by treating them with certain metallic salts, only the lake manufacturer has paid no heed to this fact.

On treating a tannin lake with a metallic salt such as certain salts of antimony, tin, zinc, lead, or iron, compound lakes are formed, and Witt has particularly showed that to produce a really bright and fast tannin lake the use of one of those salts is indispensable. Of the above mentioned salts, those of antimony proved to be superior to any other, and since the introduction of these salts, especially tartar emetic, through Th. Brooks, of Manchester, all others, except those of tin and iron, which are used for special purposes, have been practically given up. Neither the dyer nor the printer needs to be reminded of the usefulness of these salts, but the lake manufacturer has up to now never given them a fair trial.

In dyeing, the tanned cotton is always treated in the presence of a more or less considerable excess of tartar emetic or one of its substitutes, and this is of no consequence, as the tannic acid can only fix its due quantity of oxide of antimony, and, before dyeing, any excess of the latter will have been removed. In lake-making this is entirely different, and an excess of antimony salt, especially tartar emetic, would lead to results which are not intended. Tartar emetic, not through being an antimony salt, but through being a tartrate, is a very powerful precipitant of basic colours, with which it forms compound lakes by substitution of the colour base for the potassium, thus:—

These lakes are neither very bright, and still less fast, and their formation must therefore be avoided by being careful not to employ an excess of tartar emetic. Other antimony salts containing no acid capable of forming lakes with basic colours, will not precipitate the latter, and may therefore be used with greater safety.

The reaction between tartar emetic and tannic acid might be thought to occur between equal molecules of each which practically would come to equal quantities, the molecular weights of the two being 334 and 322 respectively. But on titrating a solution of tannic acid with a solution of tartar emetic according to Dr. Gerland's method, I found that each molecule of tannic acid requires only half a molecule of tartar emetic, and I satisfied myself by numerous practical experiments that indeed this proportion must not be exceeded, otherwise the lake never settles and it becomes impossible to wash it sufficiently. The lakes obtained from basic colours with the required quantity of tannic acid and the corresponding quantity of tartar emetic are beautifully bright and immensely superior in fastness to the basic colour lakes produced at present.

For reds and pinks, bichloride of tin is frequently used by the dyer in preference to tartar emetic, as the shades, especially when light, are decidedly finer, but it must also be said that they are very moderately fast only. In a similar way, of course, bichloride of tin can be used for the manufacture of free lakes in the proportion of half a molecule of tin salt for one molecule of tannic acid. It is also advisable to add always a sufficient quantity of sodium acetate in order to paralyse the free hydrochloric acid which is produced by the reaction of the tannic acid upon the tin salt.

Besides tannic acid, a great number of organic and inorganic acids are able to form lakes with basic dyes. Nearly all aromatic acids, many of the fatty acids, and of the inorganic acids, phosphoric, antimonie, arsenic, tungstic, molybdic, silicic, and others appear more or less suitable. They are, of course, all used in the form of their alkali salts. The conditions under which lakes with these acids can be obtained are far less complicated as in the case of tannic acid lakes, the reaction being essentially one of substitution of the acid of the colour salt through the acid of the precipitating alkali salt. Most of these acids or their salts must be used in considerable excess, however, to obtain complete precipitation of the colouring matter. This applies especially when dark shades are to be produced; light shades scarcely require an excess of precipitant. But, without exception, I found lakes made from any of these acids not able to bear comparison with the corresponding tannin lakes as far as fastness is concerned. Of the above-mentioned acids, only silicic acid has been suggested for the dyer's use. It can easily be fixed upon cotton by treating the latter in a solution of silicate of soda, wringing out, passing through weak soaps, and rinsing. Cotton prepared in this manner takes up most basic colours very eagerly, but the shades, which are generally very bright, are exceedingly fugitive.

Phosphates, arsenites, arseniates, and antimonates may advantageously be employed for the preparation of lakes upon a body of starch. For the same purpose tartrates, and particularly so tartar emetic, give very good results. All these mordants, if applied in conjunction with other bodies, fail to act satisfactorily, which is due to the fact that lakes on starch are made by working all through the process with as little moisture as possible, whereas those lakes precipitated on mineral bodies are always precipitated from very dilute solutions. More satisfactory are the results if the above-mentioned acids are not used in the form of their alkali salts, but in the form of some sour salt insoluble in water. Used in this way phosphoric and arsenic acid give very good results.

This process is carried out by precipitating a solution of sulphate of alumina with arsenite of soda of the formula Na_2HAsO_3 , the precipitate forms with basic colours compound lakes of great beauty, although not very fast. The chief drawback of these lakes is the large amount of arsenic they contain. In this respect the analogous alumina phosphate is quite innocent, but the lakes made from it, although good enough by themselves, are not so bright as

the former. The arsenite and phosphate of alumina used must be the acid salts of the respective formulae—

With the neutral salts of the formulae—

the shades obtained are considerably duller and much more fugitive. The cause of this is evidently the neutrality of those latter compounds, which probably are not able to react with basic colours with formation of a true lake, whereas the above-mentioned acid salts are capable of chemically assimilating the colour bases.

Not unimportant is the use which is made of the alkali salts of the fatty acids (soaps) for the production of lakes in the free state and upon the cotton fibre, the latter application being only made in dyeing and not in calico printing. Only very few basic colouring matters can be precipitated with soap solution, but in the presence of hydrate of alumina, alumina arsenite and phosphates,* and most metallic hydroxides and oxides, lakes are formed in which the fatty acid, or rather an acid salt of it, forms a constituent part. The lakes obtained under these conditions are exceedingly beautiful. But considering the little affinity between colour bases and fatty acids, it is hardly surprising to find them highly fugitive.

This method suitably modified is also used for dyeing, especially for weak shades of magenta, safranine, and methyl violet. The yarn is steeped in a soap solution for some time, wrung out and passed through a solution of tin salt, if for pink or rose shades, or through calcium chloride if for violet. After rinsing the yarns they can be dyed at once, but better results as regards fastness are obtained by taking the yarns previous to dyeing through a weak tannic acid bath. As to the beauty of the shades so obtained there is no doubt, but their fastness amounts to very little, the yarns being very much given to rubbing off.

There now remains a class of acids, which although for a high degree capable of forming lakes, have scarcely been used for this purpose. I am referring to the colour acids, the alkali salts of which are the commercial acid colouring matters. It is well known that acid colouring matters can be used as precipitants of basic colouring matters, and indeed Rawson originated an excellent process for the estimation of naphthol yellow (alkali salt of dinitronaphthol- α -sulphonic acid), by titrating it with a solution of Night blue (basic diphenylnaphthylmethane colouring matter). But most acid colouring matters are able to precipitate basic colouring matters under suitable conditions, and I believe that some of the many possible combinations may prove useful for the preparation of lakes in the free state, but scarcely for dyeing and still less for printing, as these lakes probably will not stand soap. I shall, however, have to refer to this class of lakes again in dealing with the formation of lakes from acid colouring matters, a subject I propose to bring before you at some future date.

DISCUSSION.

Mr. HURST disagreed with the author when he stated that tartar emetic was not used by lake makers, nor could he quite follow his ideas about surface attraction of these colours. He (Mr. Hurst) had precipitated them on different bases, but had never noticed much surface attraction amongst them, with the exception of Bismarck brown. Had the author noticed that when lake pigments were dried and used as oil colours they seemed slow in drying, which perhaps would account for their being so little used? In paper staining this retarding action was not noticed. He had found the same defect with pieric acid, and he attributed it to the action of the pieric acid or tannic acid on the oil.

Dr. WEBER, in reply, said Mr. Hurst evidently had not understood what he meant by surface attraction and the part it played. He must certainly be aware that if a solution of basic colouring matter were added to starch the starch would take up a great quantity and fix it without any mordant. If then a large quantity of colouring matter were added, which is precipitated with tannic acid until the precipitation appears to be complete, only that amount of colouring matter had been precipitated over and above the quantity the starch has already fixed without any tannic acid at all. Accordingly this quantity was not chemically fixed, but present in a state approaching that of a free base. He (Dr. Weber) had further shown that tannic acid precipitated much more colouring matter than it was able to fix chemically, and he had shown that under the present conditions of making these lakes scarcely ever more than half of the colouring matter was chemically fixed, but existed in the lake nearly as a free base. Taking into account the extreme sensitiveness of free colour bases against light and air, it was evident that such lakes would be extremely fugitive although the colouring matter might have been completely precipitated, which indeed could always be done without any trouble. If Mr. Hurst was of opinion that the dyer would be reluctant to observe methods of dyeing based upon scientific research he (Dr. Weber) thought the dyer would be the worse for that, as the adoption of such results could only turn out to be for his benefit. All yarns dyed in the presence of an excess of colouring matter would be defective in fastness. At present the dyer had no means of gauging the amount of colouring matter he had to apply, and means to do this was afforded by the results he obtained. He agreed with Mr. Hurst's remarks with regard to the behaviour of tannic acid lakes in oil, but it must not be forgotten that scarcely 1 per cent. of them was used in this manner. By far the largest quantity was used by paper-stainers and wall-paper manufacturers. Considering tannic acid was a monovalent acid, and considering further that the antimony radicle in the tartar emetic was also monovalent, the assumption of one molecule of tannic acid combining with one molecule of tartar emetic appeared very plausible; but the actual test he had made showed that only slightly more than half a molecule of tartar emetic was required for one molecule of tannic acid, which came very near Dr. Gerland's results.

Meeting held on Tuesday, November 24th, 1891.

SIR JAMES KITSON IN THE CHAIR.

Dorsetshire Section.

Chairman: Sir James Kitson, Bart.

Vice-Chairman: Dr. F. H. Bowman.

Committee:

A. H. Allen.	J. Lewkowitsch.
W. Brelitt.	C. Rawson
F. Fairley.	Jas. Sharp.
A. Hess.	A. Smithells.
R. Holliday.	Geo. Ward.
J. J. Hummel.	Thorp Whitaker.

Hon. Local Secretary and Treasurer:
H. R. Procter, Yorkshire College, Leeds.

Notices of Papers and Communications should be addressed to the Hon. Local Secretary.

* In this case, of course, the neutral salts are to be preferred.

INAUGURAL DINNER.

ON Tuesday, the 24th inst., Sir James Kitson entertained the members of the Yorkshire Section of the Society of Chemical Industry to dinner at the Queen's Hotel, Leeds. The gathering was regarded as the inaugural dinner of the Section, and there was a large attendance, chemists being present from all parts of Yorkshire. Sir James Kitson presided.

The CHAIRMAN, after the loyal toasts had been honoured, proposed "The Yorkshire Section of the Society of Chemical Industry." He remarked that that was not an unsuitable spot from which to propose the toast, for across the street was the house in which Dr. Priestley made his great discoveries in chemistry and in applied chemistry. Dr. Priestley in 1772 received the gold medal of the Royal Society for experiments which he made in the method of impregnating water with fixed air. Dr. Priestley wrote at Leeds a familiar introduction to the study of electricity, and in his book he recounted how, in consequence of inhabiting a house adjoining a brewery, he at first amused himself with making experiments on the fixed air which he found ready in the process of fermentation. Dr. Priestley further stated that "the only person in Leeds who gave much attention to my experiments was Mr. Hey, a surgeon, who, when I left Leeds, begged of me the earthen trough in which I had made all my experiments on air." When he thought of Dr. Priestley and the opportunities and the resources which he had, being supported only by a man taking an interest in his experiments, and contrasted that picture with the one which he now saw around him, when gentlemen from all parts of Yorkshire were present—each taking a deep personal and active interest in the application of chemistry to various industrial pursuits—he thought he was justified in saying that Leeds was not an unsuitable place in which to inaugurate the meetings of the Yorkshire Section of the Society of Chemical Industry. His position as Chairman gave him the opportunity of acknowledging how much the iron and steel industry owed to the resources and the work of chemists. He need only refer to the researches made by Sir Lyon Playfair and Sir Lowthian Bell in the examination of the gases of the blast-furnace and the actual operation of the blast-furnace to show them how much the manufacture of pig iron was indebted to these men and to the chemists who have been taught by them. He also reminded them of the great process of Sir Henry Bessemer, which had revolutionised the railway world, the manufacture of steel in this country, Europe, and America, and said that that process owed much to Sir Henry Bessemer's inspiration, his mechanical genius, but it also owed almost as much, if not more, to the researches and teachings of the chemist Mnshet. As steel manufacturers, they owed to the chemist the alloys of manganese and iron, silicon, aluminium, and the processes which were used and adopted in the open-hearth furnace. To Sir William Siemens, and more particularly to his brother, Dr. Werner Siemens, they owed the regenerative furnace, which would melt and treat as easily 20 tons of steel as 56 lb. was formerly treated in the ordinary crucible. It was wonderful to reflect upon what was done by Dr. Priestley and the early chemists with the imperfect implements and methods which were familiar to them. It was common to say that, with their Yorkshire College laboratories and with all the opportunities chemists had, they were not producing as much as the older chemists with their imperfect methods. He asserted that they were responding to their opportunities, and that chemists were producing much more than in the past. One special attribute of the chemist of to-day appeared to be the faculty of gathering up waste of every description, and the wealth he created was not subjected to the demands of labour, because all his wealth was the distinct product of his brain. He submitted the toast of the Yorkshire Section of the Society of Chemical Industry, in the belief that it would contribute not only to the prosperity of Leeds, but also of Yorkshire and the country at large.

Dr. BOWMAN, in responding, agreed with the Chairman, that when they took a retrospect of chemistry they saw a marvellous change. He felt that that inaugural gathering augured well for the future of the Section.

Mr. A. H. ALLEN also replied.

SIR LOWTHIAN BELL, F.R.S., proposed "The Parent Society," observing that he had been asked what was the function of a Society of Chemical Industry? It was, he apprehended, to bring together gentlemen occupied in the various manufactures based upon the science of chemistry, and to give them an opportunity of comparing their own experiences, and out of that elaborating some general rule which underlays the whole range of chemical industry in the country. Such a society had, as they had been told, great advantages, and the only wonder was that they had not started it earlier in Leeds, which stood on a very high pinnacle in educational matters. Long before other places had colleges for teaching physical science, Leeds had taken steps to erect in its midst a most complete and best appointed college for teaching physical science. It was also a most important thing that they had filled that college with men well qualified to discharge their duties as teachers.

Mr. C. G. CRESSWELL responded to the toast. He said the Council of the Society congratulated Yorkshire on the formation of a Section, and wished them success in their enterprise. He trusted that the number present was an earnest of those who would attend subsequent meetings. The question had been asked, What was the use of the Society? When it was founded in 1881, many friends and well-wishers said that the Society was not required, that existing societies supplied them with all the information that was necessary for the prosecution of chemistry as applied to industry. The best proof that it did supply a want was that the Society now numbered 2,700 members.

Mr. SYDNEY LUTON gave the toast of "The Chemical Industries of Yorkshire," to which Mr. HADFIELD (Sheffield) responded.

"Scientific Education in Yorkshire" was given by Mr. RICHARD REYNOLDS.

Professor SMITHIELLS, in acknowledging the toast, said the cry of technical education had penetrated the land to its utmost corners, and they were all now revelling in the grants of money which had come from one source or another in support of that cry. It had resulted in a certain impetus to institutions of a scientific character, which must be attended in the end with beneficial results. This universal dissemination of science was an exceedingly good thing, but addressing as he was a body of gentlemen representing chemical industries, he could not refrain from making the remark that he thought the advocacy of the general diffusion of science had had a fair innings, and that there remained to be advocated something for which he cordially invited their sympathy. It was no doubt a good thing to disseminate science widely, but if they came to ask themselves what would help them most in the operations in which they were daily engaged, they would not reply that it was the universal teaching of elementary science to the community at large. He had taken every opportunity of ascertaining from such gentlemen as he saw around him on that occasion what we really wanted in this country, and he gathered that what we wanted much more than the training of a large number of the population in the elementary truths of science was the training of a few to the highest possible extent. He spoke in all seriousness. This was a most important question; it was really the question of the survival and supremacy of British industries, and although he was not at all unsympathetic in regard to the demand to instruct our working men in the truths of science, he thought far more important was the instruction of the few to the very highest possible extent. There is one question which I have sometimes asked of those gentlemen who are so enthusiastic in the advocacy of technical instruction for the working classes—a question which, though it has caused annoyance, has never elicited any answer. It is this: what chemical industry is there in which foreign nations have excelled us or are likely to excel us in consequence of superior chemical knowledge of the artisans?

Mr. C. RAWSON also responded. Mr. JAMES SHARP (Halifax) proposed "The Chairman," and Sir JAMES KITSON having replied, the proceedings terminated.

Glasgow and Scottish Section.

Prof. W. Dittmar, "The Availability of Metallic Vessels for Chemical Operations in the Laboratory."

Mr. D. J. Playfair, "Notes on the Production of Cyanides."

Meeting held in the Societies' Rooms, 207, Bath Street, Glasgow, on Tuesday, 3rd November 1891.

MR. C. A. FAWSITT IN THE CHAIR.

NOTE ON THE PRECIPITATION OF PHOSPHORUS FROM SOLUTIONS OF IRON AND STEEL.

BY ROBT. HAMILTON, F.R.C.S.

THE rapid and correct estimation of phosphorus in iron and steel is of such technical interest and importance, that I imagine any information concerning it will be welcome to many members of our Society.

Of the many methods proposed for this estimation, that chiefly employed is one form or other of the method depending on the precipitation of the phosphorus as ammonio-phospho-molybdate, often spoken of as "yellow precipitate."

It was known for many years that unless certain precautions were taken in dissolving the sample, there was a liability to obtain a solution from which the ammonium-molybdate solution would not precipitate the whole of the phosphorus.

In 1877, And. A. Blair and Finkner independently attributed this interference to the presence of carbonaceous matter in the solution, derived from the action of acids on the combined carbon of the metal, and they directed that the operation of solution should be conducted in such a manner as to destroy these carbonaceous compounds. This was practically effected by evaporating the acid solution to dryness and roasting the residue.

Adolf. Tamm (Chem. News, 1884), accentuated the same view.

There are methods founded on the afore-mentioned observations which leave nothing to be desired in point of accuracy; but the evaporation to dryness with subsequent roasting and re-solution, consumes much time, besides the minor inconvenience caused by large amounts of acid fumes.

Having a considerable amount of work to get through, I naturally neglected no opportunity of trying processes which promised to save time, and I may preface my further remarks by saying that my object was to obtain a rapid process for the correct estimation of phosphorus in hematite pig iron.

In 1888, P. W. Shimer suggested that the incomplete precipitation of phosphorus was due to incomplete oxidation of the phosphorus, and proposed to render all the phosphorus precipitable by oxidising the solution with potassium permanganate, &c.

The experiments recorded in this paper would appear to show that this view has much to commend it.

For the estimation of the phosphorus, Shimer used the filtrate from the determination of silicon by the nitric and sulphuric acids method. It was tried at the time with unsatisfactory results, though I now believe that with a little practice, good results could be obtained; but the method presented no advantages over the one I then used, and it was not followed up.

In 1889, Dr. Brown supported Shimer's idea and introduced an important improvement conducing to rapidity, namely, the solution of the metal in *dilute* nitric acid, thus retaining practically the whole of the silica in solution, but in this case the yellow precipitate should not be weighed, but, if large enough, should be converted into magnesium pyrophosphate; or, if too small for that, may be reduced with zinc and the solution titrated with standard permanganate. This method was carried out at the time exactly as described (Chem. News, July 1889) and unsatisfactory results obtained.

At intervals there continued to appear in the journals slight modifications of the foregoing methods, and the advantages offered were so tempting that I determined to perform a few experiments to find out whether the idea was a correct one or not. Though the process was wanted ultimately for hematite iron, yet the proportion of phosphorus in that iron is so small that experimental error forms a larger factor and renders the results less decisive than if operating with an iron containing more phosphorus; besides it is desirable to weigh the phosphorus as magnesium pyrophosphate whenever possible, so I determined to work with phosphoric iron.

First, to see what effect the presence of the carbonaceous matter had, a sample of hematite white pig-iron was selected, low in phosphorus and high in combined carbon.

A full analysis was not made, but the following figures will give a fair idea of its composition: phosphorus, 0.037 per cent.; silicon, 0.71; sulphur, 0.26; graphite, a trace; and combined carbon fully equal to that of a pig to be mentioned further on, which had 2½ per cent. of combined carbon.

The general details of the method followed are much the same in each case, and I shall describe the first experiment fully, and only detail the *differences* in those following.

Experiment No. 1.—25 grains sample plus 500 measured grains of nitric acid (1.2), evaporated till a good deal of iron salt dried, taken up with hydrochloric acid, evaporated to small bulk, diluted, filtered, evaporated till skin just began to form, added excess of ammonia, then a slight excess of nitric acid, then molybdate solution, gave yellow precipitate, equal to 0.30 per cent. phosphorus, equal to 81 per cent. of the phosphorus present.

A solution of phosphoric acid was prepared of such strength that 100 measured grains contained about 0.25 grain of phosphorus, so that 100 grains of the phosphoric acid solution added to 25 grains of the pig-iron, came to about the same thing as working with a sample of iron containing 1 per cent. of phosphorus.

Experiment No. 2.—25 grains iron plus 500 grains nitric acid (1.2), heated till all dissolved, added 100 grains phosphoric acid solution, then proceeded with as before, gave magnesium pyrophosphate equal to all the phosphorus added as phosphoric acid, plus that derived from the sample of iron used.

Experiment No. 3.—25 grains iron, plus nitric acid and phosphoric acid as last, evaporated till the solution would just run, but no iron salt dried, then exactly as before, gave the whole of the phosphorus present.

Experiment No. 4.—A repetition of the last gave the same result.

Experiment No. 5.—25 grains iron, plus nitric acid and phosphoric acid as before, but evaporated only to half bulk, and without filtering proceeded with as before, gave the whole of the phosphorus present. The filtrate from the yellow

precipitate was dark sherry-coloured, and the ammonio-magnesium-phosphate was mahogany coloured.

Experiment No. 6.—To test if the action of solution had any effect on the phosphoric acid, 100 grains of the phosphoric acid solution was measured out, 25 grains iron added, then nitric acid, evaporated to half bulk, and proceeded with as last, gave the whole of the phosphorus present; colours of solutions and precipitates same at last.

These experiments seemed to prove that the presence of carbonaceous matter in solution did *not* prevent the precipitation of phosphorus which existed as phosphoric anhydride in combination.

The next step was to find out if the phosphorus in iron could be rendered completely precipitable by oxidation while in solution. For this purpose the following experiments were made with a sample of white pig iron, made when a furnace was being blown in, of the following unusual composition:—

WHITE PIG IRON (PHOSPHORIC).

	Per Cent.
Graphite	0.67
Combined carbon	2.54
Total carbon	3.21
Silicon	0.30
Phosphorus	1.36
Sulphur	0.20
Manganese	0.60
	5.85
Iron (by difference)	94.15
	100.00

For the remainder of this paper, when iron is mentioned, this white iron with 1.36 per cent. of phosphorus is meant.

Experiment No. 7.—25 grains iron plus 500 grains nitric acid (1.2), evaporated to half bulk, added excess of ammonia, slight excess of nitric acid and molybdate solution. Phosphorus finally weighed as magnesium pyrophosphate equalled 70 per cent. of the phosphorus present. The filtrates were all tested, but this one was especially worked with, but no more yellow precipitate was obtained.

At experiment No. 8, I began to try the effect of oxidising agents. 25 grains iron plus 500 grains nitric acid (1.2), boiled, plus three additions of 100 grains each of 10 vol. hydrogen peroxide, boiling between each addition, evaporated to half bulk, and proceeded with as before, gave magnesium pyrophosphate equal to 95 per cent. of the phosphorus present.

The hydrogen peroxide destroyed the combined carbon colour, the solution became clear and the precipitates were pure yellow and white respectively.

It is hardly necessary to mention that the hydrogen peroxide and other chemicals used were tested for phosphorus.

Experiment No. 9.—25 grains iron treated as last, the only difference being that five additions of hydrogen peroxide of 100 grains each were made, instead of three as before, gave magnesium pyrophosphate equal to 99.3 per cent. of the phosphorus present.

To avoid the boiling between each addition of hydrogen peroxide, the following experiment (No. 10) was tried:—25 grains iron plus nitric acid, boiled, cooled, added 200 grains of a fresh solution of 20 vol. hydrogen peroxide, allowed to stand for 20 minutes, then heated very slowly and boiled down to half bulk, then as before, gave magnesium pyrophosphate equal to only 85 per cent. of the phosphorus present.

Small additions of hydrogen peroxide, boiling after each addition, seemed to render all the phosphorus precipitable, but the cooling between each addition was a loss of time, besides there was nothing to show when enough of the oxidising agent had been added.

In Shimer's paper it is directed to add the permanganate solution (the oxidising agent he used) till a precipitate of hydrated manganese peroxide comes down; this seemed a useful, visible reaction, and it was resolved to test it.

For experiment No. 11, 25 grains iron were taken plus 500 grains nitric acid (1.2), boiled, and a solution of permanganate added till the desired precipitate came down; the solution cooled, 20 drops hydrogen peroxide added, boiled, neutralised with ammonia, boiled again with a little permanganate till a precipitate came down, which was removed again with hydrogen peroxide, the solution evaporated to half bulk and proceeded with as before, gave magnesium pyrophosphate equal to 99.7 per cent. of the phosphorus present.

The use of hydrogen peroxide for deoxidising the manganese peroxide precipitate is both elegant and effective, but as the solution requires to be cooled to about 130° F. before adding it, there is a slight loss of time.

Shimer dissolved the manganese peroxide precipitate in hydrochloric acid, and Drown removed it with an organic acid or with sugar. When trying Drown's method, I had used tartaric acid, but had not got satisfactory results with it, and Jones (Chem. News, 1890) found the same thing and proposed the use of ferrous sulphate.

Five experiments were performed very much the same as the most successful of the experiments already mentioned, oxidising the solution with permanganate, and removing the manganese peroxide precipitate with ferrous sulphate; without going into details, I may say that the lowest result equalled 94.1 per cent. and the highest, 96.3 per cent. of the phosphorus present.

In each of the foregoing experiments (excepting two of the five with ferrous sulphate) the yellow precipitate was allowed to settle for hours, usually overnight, but to save time I now tried the effect of shaking for five minutes as proposed by Emmerton, and filtering straight off.

Experiment No. 12.—25 grains iron plus 700 grains nitric acid (1.135, being the strength recommended by Drown for keeping the silica in solution), oxidised twice with permanganate, removing the precipitate with hydrogen peroxide and neutralising with ammonia between the two oxidations, the flask stoppered and shaken vigorously for five minutes, cooled and filtered, gave magnesium pyrophosphate equal to 96.3 per cent. of the phosphorus present.

Experiment No. 13.—The above experiment repeated, gave 100 per cent. of the phosphorus present.

Even a single oxidation gave very fair results, as follow:—

Experiment No. 14.—25 grains iron plus 700 grains nitric acid (1.135), oxidised with permanganate and hydrogen peroxide, neutralised with ammonia, molybdate solution added, shaken for five minutes, cooled and filtered, gave magnesium pyrophosphate equal to 96.3 per cent. of the phosphorus present.

Experiment No. 15 is exactly similar to the last, that is, the solution was only oxidised once, but the yellow precipitate was allowed to stand for 1½ hours before being filtered off, and the magnesium pyrophosphate obtained was equal to 100 per cent. of the phosphorus present.

The magnesium pyrophosphate precipitates from five experiments in which dilute nitric acid had been employed, were added together and tested for silica by evaporating to dryness with hydrochloric acid, &c.; the insoluble matter weighed only 0.09 grain, which may fairly be allowed to have been derived from the filter ashes, and evidently the precipitates have been free from silica.

At this point I may refer to an experiment of some interest, only completed this morning.

Experiment No. 16.—In this experiment I took 25 grains of the white phosphoric iron, added 500 grains nitric acid (1.2) and boiled, neutralised with ammonia, and precipitated with molybdate solution. The flask stood a few hours, the precipitate had settled thoroughly and left a clear liquid which was decanted through a filter and the precipitate washed once.

To the clear filtrate I added permanganate solution and placed it on the water-oven; in a short time the liquid became turbid, and deposited yellow precipitate. After standing about one hour I added excess of hydrogen peroxide and allowed it to settle over night; when filtered and weighed this morning, the yellow precipitate equalled 33 per cent. of the phosphorus in the pig iron. Referring to experiment No. 7, it will be observed that it is so far much the same as No. 16, only the original nitric acid

The causes of explosion are arranged under three heads:—

A. Faults of Construction or Material, which may be detected before starting or after Repair. B. Faults of Inspection. C. Faults which could be detected by Attendants.

	No.	Killed.	Injured.
<i>A. Bad weld</i>	3	0	0
Plug blew out	1	0	0

PATENTS.

Improvements in Lining Boilers or Digesters used in the Manufacture of Paper Pulp and for similar Purposes. C. Kellner, Vienna, Austria. Eng. Pats. 15,930 and 15,931, October 8, 1890. 4*d.* each.

See under XIX., page 944.

Improved Means of Manufacturing Glass Vessels and Adapting the same for the Storage and Conveyance of Compressed Gases and for Similar Purposes. D. Rylands, Stairfoot. Eng. Pat. 17,117, October 27, 1890. 8*d.*

See under VIII., page 927.

An Improved and Completed System of Apparatus for Evaporation and Distillation. P. Callibacès, Paris, France. Eng. Pat. 17,237, October 28, 1890. 1*s.* 1*d.*

This invention comprises three apparatus, one employed for the evaporation and distillation of liquid, the other two complementary evaporating apparatus, intended to serve for completing the treatment effected in the principal

apparatus, and for obtaining a complete concentration of the liquid until it has lost its fluidity. For details the specification and drawings attached should be consulted. There are 10 claims.—E. S.

Improvements in Apparatus for Distilling Sea Water and other Water containing Foreign Matter or Impurities.
A. Normanby, London. Eng. Pat. 17,939, November 7, 1890. 8d.

THE improvements described are particularly applicable to apparatus for use on board steamships. An outer chamber encloses a second one, containing preferably a number of pipes. A regulated supply of sea water is admitted automatically into the outer chamber, so as to entirely cover the inner chamber. Steam is admitted into the inner chamber, and being condensed by the surrounding sea water escapes by a small opening, and returned to the boiler. The heat of the steam inside the pipes evaporates a portion of the sea water, and the secondary steam thus formed rises into the upper part of the outer chamber, and escaping through a steam valve to the condensers is used for feeding the boiler, or by passing through a second steam valve to a condenser may be used as drinking water. This latter condenser consists of an outer chamber in which is an upper and a lower chamber formed of tubes and communicating with each other. The secondary steam being condensed into hot fresh water in the upper chamber passes into the lower chamber to be cooled by the colder water circulating outside, and thence into the drinking water tanks.—E. S.

Improvements in the Filling of Cylinders or other Receivers with Oxygen, Hydrogen, Coal, Oil, and other Gases, or Mixtures of Gases under Pressure. J. H. Parkinson, Manchester. Eng. Pat. 18,445, November 15, 1890. 8d.

THE object of this invention is to provide means by which suitable vessels may be filled with compressed gas without the aid of compressors or pumps. Several storage cylinders of as large a capacity as can be readily transported from place to place are charged with the gas under a pressure much higher than that required to fill the receivers, with which they are connected by suitable valves. A safety valve or pressure gauge may be added to indicate when the required pressure of gas is obtained in the cylinder being filled.—E. S.

Improvements in Filtering Apparatus. L. A. Philippe, Paris, France. Eng. Pat. 534, January 10, 1891. 1s. 1d.

THIS invention relates to filtering apparatus, having either simple or multiple pockets, and the improvements consist in the mode of fixing the pockets by which their sides are kept at a distance from each other; and also in a contrivance by which the filter can be emptied without turning over the apparatus. For details of construction the specification and four sheets of drawings attached to it must be consulted.—E. S.

Improvements in Pumps for Petroleum, Oil, Spirit, Varnish, and other Liquids. F. A. Vichweg, Falkenstein, Germany. Eng. Pat. 12,415, July 16, 1891. 6d.

THE improvements consist in constructing a pump which can be readily emptied after use (by simply raising the top lid and pressing the piston rod deeper than when in ordinary use), and in which the liquid is prevented from splashing out above it. The first mentioned improvement is especially applicable to out door pumps in protecting them from the effects of frost. For details the specification must be referred to.—E. S.

Improved Apparatus for the Desiccation of Solid Matters.
E. Donard and G. Boulet, jun., Rouen, France. Eng. Pat. 12,542, July 23, 1891. 6d.

THE material to be treated having been suitably prepared is introduced by a suitable opening into the body of the evaporator through which heating tubes pass. This opening being hermetically closed, a vacuum is formed by an air pump and condenser. Steam is admitted through one portion of the hollow shaft, and the apparatus is caused to revolve. Through the combined effect of the heat and vacuum, evaporation begins at once, and the vapour so produced passes through another portion of the shaft into a condenser connected with the air pump. The low temperature at which desiccation is carried on allows the animal and vegetable substances operated upon to retain all their nutritive qualities. A modification of the apparatus is also shown in the specification drawings, in which coils and double shells are employed instead of tubes.—E. S.

Comparative Experiments on Boiling with Coal-Gas and Water-Gas. D. Coghevin. Jour. f. Gasbeleuchtung, 1891, 34, 334—335.

THE author has made comparative experiments on boiling with various types of apparatus used for cooking purposes in Austria. Three principal types of apparatus were selected:—(1.) A vertical boiler in common use, made on a French model, and furnished with two rows of flames. (2.) The well-known boiler made by the German Continental Gas Company in Dessau. (3.) An Austrian boiling apparatus with triangular slit opening. The results stated below are for the best of each type. The temperature of the room throughout the experiments was 14°, the gas pressure was equal to 2 cm. of water, and the amount of water used in each experiment was 1 litre. It was found that the amount of heat (in calories) generated in each case *per minute* was, with coal-gas—

	Cal.
1. French boiler	167.00
2. Dessau boiler	187.80
3. Austrian boiler	147.28
Mean	167.66

The amount of heat generated *per cubic metre* of coal-gas used was:—

	Cal.
1. French boiler	21867.0
2. Dessau boiler	23847.6
3. Austrian boiler	20087.0
Mean	22217.2

Taking the theoretical heating effect of 1 cubic metre of coal-gas as 5150 cal., these results show that the best types of apparatus have an efficiency of $\frac{22217.2 \times 100}{5150} = 43.13$ per cent.

Experiments were next undertaken with the object of investigating the efficiency of the same types of boiling apparatus when used with water-gas instead of coal-gas. It was found necessary to close the air openings and to increase the gas pressure up to 6 cm. of water. Under these circumstances the following results were obtained:—

The amount of heat (in calories) generated *per minute* with water-gas :—

	Cal.
1. French boiler	12'43
2. Dessau boiler	13'14
3. Austrian boiler	10'60
Mean	11'76

The amount of heat generated *per cubic metre* of water-gas used was :—

	Cal.
1. French boiler	942'0
2. Dessau boiler	1081'4
3. Austrian boiler	1036'4
Mean	1019'9

Taking the theoretical heating effect of 1 cub. metre of water-gas as 2813 cal., these results show that the best types of apparatus have an efficiency of $\frac{1019.9 \times 100}{2813} = 36.25$ per cent.

The author is of opinion that the commonest fault in all types of boiling apparatus (whether for coal- or water-gas) lies in the fact that the flame only plays on parts of the bottom of the boiler. Improvements can best be effected by securing an even spreading out of the flame.—D. E. J.

The Behaviour of Impure Materials in the Amyl Acetate Lamp. F. von Hefner. Jour. f. Gasbeleuchtung, 1891, 34, 349—351.

As the question of the effect of impure materials on the illuminating power of the amyl acetate lamp has recently been raised (compare this Journal 1891, 685) the author has made a number of experiments in this direction with samples of amyl acetate containing various impurities, which were likely to be either present in, or added to, the commercial article. A sample of amyl acetate, to which castor oil was added in such quantities that the adulteration could not be detected by a specific gravity determination, was also investigated. The following results were obtained :—

SAMPLE I.

Composition { Amyl acetate..... 80 per cent. } Moist	
{ Fusel oil..... 20 " }	
Sp. gr. 0'8645 at 15°. Boiling point..... 100'5—142°	
Boiling point with reflux condenser..... 106'5°	
Liquid consumed in half an hour after ignition. 4'98 grms.	
Deviation from the normal consumption... + 6'9 per cent.	

Illuminating power clearly too low, on the average about 2 per cent.

Position of wick a little higher than the normal.

SAMPLE II.

Composition { Amyl acetate..... 95 per cent. }	
{ Diamylene..... 2 " }	
Sp. gr. 0'8725 at 15°. Boiling point..... 136—142°	
Boiling point with reflux condenser..... 139'5°	
Liquid consumed in half an hour after ignition 4'62 grms.	
Deviation from the normal consumption... — 0'8 per cent.	

Illuminating power on the average the same as that of pure amyl acetate, greatest difference ± 1.5 per cent.

SAMPLE III.

Composition { Amyl acetate..... 91 per cent. }	
{ Alcohol..... 5 " }	
{ Castor oil..... 4 " }	
Sp. gr. 0'8745 at 15°. Boiling point..... 120—142°	
Boiling point with reflux condenser..... 120°	
Liquid consumed in half an hour after ignition 4'94 grms.	
Deviation from the normal consumption... + 6 per cent.	

The illuminating power could not be determined with accuracy.

SAMPLE IV.

Composition { Amyl acetate..... 80 per cent. }	
{ Isobutyl acetate..... 10 " }	
{ Amyl alcohol..... 10 " }	
Sp. gr. 0'869 at 15°. Boiling point..... 133—142°	
Boiling point with reflux condenser..... 133°	
Liquid consumed in half an hour after ignition 4'61 grms.	
Deviation from the normal consumption... — 0'4 per cent.	

Illuminating power practically the same as that of pure amyl acetate, on the average 0.4 per cent. higher.

SAMPLE V.

Composition { Amyl acetate..... 50 per cent. }	
{ Alcohol..... 50 " }	
Sp. gr. 0'8408 at 15°. Boiling point..... 81—142°	
Boiling point with reflux condenser..... 81°	
Liquid consumed in half an hour after ignition 6'16 grms.	
Deviation from the normal consumption... + 39 per cent.	

Illuminating power about 40 per cent. too low.

SAMPLE VI.

Pure amyl acetate. Sp. gr. 0'8735 at 15°. Boiling point	
136—142°, with reflux condenser 139'5°	
Liquid consumed in half an hour after ignition 4'66 grms.	

The composition of the above samples is given by weight.

The quantity of liquid consumed was determined by first burning the lamp for about 15 minutes, the flame being carefully adjusted to the normal height; the lamp was then extinguished, weighed, lighted again, and allowed to burn for exactly half an hour; the loss in weight was then determined with the results given above. The height of the barometer varied during the experiments from 767 to 758 mm., and the temperature from 15.5° to 20°.

The results of this investigation, taken in conjunction with others previously published, show that for all practical purposes the illuminating power of the amyl acetate lamp is not appreciably affected by the employment of commercial amyl acetate containing the most frequently occurring impurities. In the case of those impurities which have a considerable effect on the illuminating power, the rate of consumption is also materially altered; an increased consumption may, however, be accompanied by a decrease in illuminating power, and vice versa.—F. S. K.

Giraud's Thermo-Electric Stove. E. Hospitalier. Le Génie Civil, 19, 1891, 30—46; and Abs. Proc. Inst. Civil Eng. 105, 1891, 83—84.

THE author refers to the want of success which has attended the use of thermo-electric batteries as sources of energy, and to the large consumption of gas which is found necessary, so that only about 0.5 per cent. of the thermal energy is obtained in the outside circuit for lighting purposes. He believes, however, that the problem is entirely different where it is possible to use the combustion of the gas or coal for heating purposes, and the thermo-electric stove brought out by Dr. Giraud, of Chantilly, fulfils the latter requirement. The stove resembles an ordinary stove used for heating purposes so far as its exterior is concerned. The products of combustion, however, rise vertically in a cylindrical chamber, and descend between this and a second envelope concentric with the chamber before passing to the chimney. This arrangement protects the metallic contacts from excessive heating, and equalises the temperature to which they are exposed. The heated gases come into contact with a series of rectangular boxes of stamped iron plate, forming a kind of cylindrical hive or chequer work, in which are placed the thermo-electric elements. These elements, to the number of about 700, are placed in the large pattern of stove in a series of 25 horizontal rings, and in a smaller type shown in the figures in a

series of 18. The elements consist of couples of nickel or tinned iron (tin-plate) and an alloy mainly composed of zinc and antimony, to which other metals are added in small quantities in order to increase the strength and retard fusion. The elements, which are set in cells in the stamped plate, are insulated by a coating of asbestos; cooling is effected partly by the wing shape of the elements and partly by the circulation of air between them. The whole of the 700 elements are joined in series and give practically the same electro-motive force whether nickel or tinned iron is employed. The electro-motive force at full power is about 40 volts, and the current in short circuit 1 ampère. At its maximum useful power, which is the only point necessary to consider, as the consumption of combustible matter is independent of the energy of the battery, the useful output is 40 watts, equal to about 1 kilowatt-hour per day for continuous working. The consumption of coke to effect this result is about 61·6 lb. per day, and with coke costing 27·5*d.* per cwt. the cost per kilowatt-hour would be 15*d.*, which is exactly the maximum price demanded by the central stations in Paris. As the output is too small to supply more than one lamp coupled direct, it is necessary to use accumulators, which raise the cost of the installation and reduce the quantity of electricity obtainable. In reality the electricity is obtained more expensively than from the central stations; but it must be remembered that the heating of the rooms is also obtained.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Production of Ozokerite in the United States. E. W. Parker. Eng. and Mining J. 1894, 127.

OZOKERITE, or "mineral wax," belongs to the series of hydrocarbon compounds which include marsh-gas, petroleum, and paraffin, it being very similar in appearance to the last. It is colourless to white when pure, but frequently occurs black-green, yellow, and brown. Prior to 1888 the only locality producing this mineral was in the province of Galicia, in Austria. Mining began there in 1862, and, though at first it was found exceedingly difficult to obtain sufficient capital to push the enterprise, it has increased rapidly since that date, and at present there are 35 companies engaged in the industry in the province of Galicia alone. For 26 years production was limited to this locality, but in 1888 American ozokerite began to receive the attention of the trade, and considerable work was begun upon a newly discovered vein in Utah. The mineral had been known to exist in Utah for some years, but whether in paying quantity was not satisfactorily determined until August 1888.

During 1888 and 1889 most of the work done was in the way of development, but in the latter year there were incidentally produced 75,000 lb. of crude ozokerite. Of this product 33·33 per cent. is lost in refining, the amount of refined ozokerite being 50,000 lb., valued at 2,500*dols.* The product of 1888 was estimated at 65,000 lb. of crude mineral. The product for 1890 will probably exceed 300,000 lb.

Refined ozokerite is used for nearly all the purposes to which ordinary beeswax is applicable. It possesses nearly all the properties of beeswax except stickiness, but in cases where that quality is essential it is necessary only to mix the mineral with ordinary beeswax. Crude ozokerite, like other hydrocarbon compounds, is used to a considerable extent as an insulator for electrical wires.

The following table shows the quantity and value of crude and refined ozokerite imported into the United States from 1873 to 1889, inclusive:—

Year.	Quantity.	Value.	Year.	Quantity.	Value.
	Lb.	\$		Lb.	\$
1873	25,135	4,244	1882	272,500	20,322
1874	380	40	1883	565,658	52,774
1875	7,430	1,026	1884	617,992	60,026
1876	16,525	2,229	1885	1,056,438	123,976
1877	101,604	11,720	1886	800,496	71,220
1878	69,884	7,578	1887	718,760	50,084
1879	44,963	6,016	1888	1,164,940	80,131
1880	103,973	14,057	1889	1,078,725	86,682
1881	98,911	12,792			

Asphaltum and Ozokerite in the United States. E. W. Parker. Eng. and Mining J. 1891, 193—194.

GILSONITE, elaterite, uintahite, wurtzilite, albertite, grahamite, asphaltum, maltha, and breu are names given to various semi-solid bitumens which differ considerably from one another in their chemical composition, in their action with acids or other agents, and upon the application of heat, but are considered under the head of asphaltum in this report.

No statement of the production of asphaltum is given in the Tenth Census reports. From 1882 to 1885, inclusive, the product was estimated at 3,000 short tons per year, having an average value of 10,500*dols.* In 1886 the production increased slightly, being 3,500 short tons, value 14,000*dols.* In 1887 a still further increase was noted; the product was 4,000 short tons, value 16,000*dols.* The production each year was limited to California. The figures for 1888, as published in the "Mineral Resources of the United States," show a remarkable increase, due to the production in California of 50,000 tons of bituminous rock (a sandstone formation impregnated with asphaltum), which then came into the market as a competitor with other kinds of material for street paving. In addition to this, 450 tons of gilsonite, valued at 22,500*dols.*, were produced in the territory of Utah. The value of the total product was estimated at 331,500*dols.*, but in this aggregate the value of bituminous rock was taken at the price free on board cars. The value at the mines was about 165,000*dols.*

The following table shows the product of asphaltum and bituminous rock for the United States for the calendar year 1889:—

States.	Product.	Value.
	Short Tons.	Dols.
California (bituminous rock)	47,968	125,885
Kentucky (bituminous rock)	112	252
Utah (bituminous rock)	3,163	15,000
Utah (gilsonite)	492	29,400
Total	51,735	171,537

Sources of Asphaltum.—Although for a number of years asphaltum in different forms has been known to exist in California in large quantities, it was not until 1888 that its production assumed any important proportions as an

industry. In 1888 a large deposit of bituminous rock containing an unusually large percentage of asphaltum was discovered in Ventura county, and a company of San Francisco capitalists was organized for the purpose of developing and operating it. The owners styled this mineral "asphaltum," but, as it contained but 24 per cent. of bitumen, the other constituents being silica (about 64 per cent.), oxide of iron, and calcium carbonate, it should be classed among the bituminous rock products. Its high percentage of bitumen, however, increases its value, and the price ranges from 8 dols. to 10 dols. per ton, while the bituminous rock of San Luis Obispo and Santa Cruz is valued at about 2.50 dols. per ton at the mines.

There are several deposits of bituminous rock in San Luis Obispo and Santa Cruz counties, in which the peculiar features of asphaltum formations are strikingly illustrated, clearly showing that they belong to no particular era or age; that they are found at various altitudes, and with no uniform character in appearance, hardness, or chemical composition. Deposits of solid asphaltum and springs of viscid, oily material, commonly called "brea," occur in places not a thousand feet apart, and yet in strata of unquestionably different periods of formation.

Until the remarkable impetus given to the asphaltum industry in California and Utah in 1888, the island of Trinidad and the deposits of Seyssel, in France, and Val-de-Travers, in Switzerland, furnished the bulk of the world's supply. Cuba produces asphaltum of excellent quality, some of which has been imported into the United States. Venezuela has furnished a small portion of the supply in the past, and a few tons of bituminous limestone are imported annually from Germany and the island of Sicily. In the State of Talasco, Mexico, large deposits of asphaltum are reported, but, although at a convenient place for shipment over the Mexican National Railway, only a few small lots have been shipped.

Preparation for Street Pavements.—The principal use of asphaltum, as is well known, is for street pavements. The bituminous limestone of France and Switzerland is prepared for this purpose by being first ground to a fine powder, then passed through iron cylinders, into which air heated to a temperature of 500° F. is introduced. It is thoroughly stirred as it passes through the cylinder, and when it reaches the opposite end is removed in a plastic condition and spread upon a concrete foundation, compacted by rammers, and when cool the street is ready for use.

The Trinidad asphaltum, upon being unloaded at its point of destination, is placed in large tanks and heated over a slow fire for a few days, care being taken not to heat the mass sufficiently to cause distillation. By this process all foreign substances are eliminated; vegetable impurities rise to the top and are skimmed off, while the earthy constituents settle to the bottom, and the asphaltum is then in a condition for manufacture. For street paving the refined asphaltum is treated with the residuum of petroleum, and mixed with fine sharp sand in the proportion of 14 per cent. by weight or 25 per cent. in bulk of asphaltum. The mixing is thorough, and is made at a temperature of about 300° F. While still hot and plastic it is spread upon the foundation already prepared and rolled by heavy steam rollers. The advantage claimed for the Trinidad asphaltum over the French and Swiss limestone material lies chiefly in the granular nature of the sand used in preparing it, which prevents the slipping of horses.

Gilsonite is prepared for this purpose by being first pulverised and mixed with petroleum oil. The mixture is then heated, care being taken to keep the temperature below 500° F., as above that temperature gilsonite will decompose. This composite is mixed while heated with broken stone or gravel, and is then ready for the street. It has been ascertained that a mixture of about 80 per cent. gravel makes the most durable pavement.

For the manufacture of street paving from the bituminous rock of Ventura and Santa Barbara counties, Cal., it is only necessary to mix it when heated with the sand of the locality where it is used. Sand is mixed with the asphaltum in the proportion of from three to eight times by bulk of sand to one of asphaltum. This method effects a considerable saving in transportation expenses. There is no appreciable

loss of time in placing it on the street, as it requires only an hour after laying to "set" and be ready for traffic. Once properly mixed and laid it seems practically indestructible, as shown by a section of this pavement which had been in use for 18 months in one of the streets of San Francisco.

The bituminous rock of San Luis Obispo and Santa Cruz counties, California, is a sandstone thoroughly impregnated with bitumen. It is used almost entirely for street paving, and for that purpose is probably more easily and cheaply prepared than any of the asphaltum products. The only treatment necessary is to steam it, so as to thoroughly mix its ingredients and soften it for spreading to a uniform thickness and a smooth, even surface. Bituminous rock has supplied a limited local demand for 10 or 15 years, but it is only during the past two years that it has assumed any commercial importance as an industry. It is reported that pavements made of this material 15 years ago and used under heavy travel have recently been removed, and found to have lost very little either in weight or thickness; also that it stands equally well the high temperatures of the interior cities and the cold damp atmosphere of the coast. It is estimated that there are now 50 miles of bituminous rock street pavement in the State of California.

Although the production of bituminous rock in California and of gilsonite in Utah have assumed proportions of commercial importance, with indications of much greater activity in the near future, the island of Trinidad continues to be the main source of supply for the United States. In the Eastern cities, Trinidad asphaltum is used for street paving, to the almost entire exclusion of other kinds. This is due entirely to its advantage in cost of transportation. The railroad freight rates from the Pacific Coast practically shut out the bituminous rock of California from competition in the Eastern States, and a similar condition may be said to affect the sale of Trinidad asphaltum in the cities of Europe, since the bituminous limestones of Val-de-Travers and Seyssel, having the advantage in freights, control the markets. The cost of preparing the different varieties of asphaltum for street pavement is nearly the same, and, as all appear to be about equally durable, the exclusive use of any one of them is due merely to the advantage in freights.

Comparative Prices.—The ruling prices for the different varieties of asphaltum during the year 1889 were as follows:—Trinidad, crude, at New York, 13 dols. per ton; Trinidad, refined, at New York, 30 dols.; hard Cuban, at New York, 28 dols.; gilsonite, at the mines, 60 dols.; bituminous rock, California, at the mines, 2.50 dols. to 10 dols.; bituminous rock, Kentucky, at the mines, 2.40 dols.; prime Cuban, at New York, 4.5 to 5.5 cents per pound.

Other Uses.—Although the greatest use for asphaltum is in the manufacture of street paving, large quantities are consumed in making floors for warehouses, cellars, "wineries," breweries, &c. It is used for lining dams, levees, and reservoirs, and as a coating for piling, wharf timbers, ground ends of telegraph poles, &c. It is also used as a cement for sea walls and other marine architecture, and to protect iron work subjected to action of salt water from corrosion. It is to a considerable extent used as a roofing material, and, being practically a non-conductor of electricity, serves a useful purpose as an insulator for electrical wires. Varnish is manufactured from refined asphaltum or gilsonite by simply heating with spirits of turpentine.

New Discoveries.—Asphaltum deposits have been found in some of the north-western counties of Alabama, and some progress has been made in the way of developing the properties, but none of the mineral had been mined up to the close of the year 1889. Other deposits are reported in Grayson and Hardin counties, Kentucky, on which partial developments have been made, but the owners are waiting a more lucrative demand. In Burnet county, Texas, asphaltum is known to exist, but little authentic information is obtainable regarding its extent and character.

Imports.—The imports of Trinidad asphaltum by all companies in 1889 amounted to 52,881 long tons, and in 1890 to 54,692 tons. About 800 tons of asphaltum were imported from Cuba in 1881 and 1882, but there have been

no importations of any consequence since 1882. During 1885 and 1886 about 500 tons were obtained from Venezuela, but no amount of any importance has been imported into this country from there since that time. From Neuchâtel, Switzerland, and Seyssel, France, the imports of bituminous limestone, sometimes called "asphalte," are about 200 tons annually, and about 150 tons of a similar material are imported each year from Hanover and Brunswick, Germany. All of this material was used in laying sidewalks and for interior work. During 1887, 1888, 1889, and 1890 about 6,000 tons of bituminous limestone were imported from Sicily and used for street paving.

Asphaltum Pavements.—The number of square yards of Trinidad asphaltum laid in the United States in the past decade is as follows: 1880, 106,838; 1881, 116,629; 1882, 196,184; 1883, 387,510; 1884, 424,524; 1885, 403,882; 1886, 623,188; 1887, 799,335; 1888, 757,101; 1889, 1,120,863; 1890, 1,857,000; total, 6,803,054, which is equivalent to 446 miles of roadway 26 feet wide. Trinidad asphaltum is being used for street paving in 49 cities in the United States and Canada.

From the best information obtainable the proportions of Trinidad asphaltum used for different purposes are about as follows: For laying sheet asphalt pavements 72 per cent., for manufacturing asphalt blocks and tiles for pavements, 24 per cent., total for paving, 96 per cent.; for roofing, 3 per cent.; for all other purposes, 1 per cent.; total, 100 per cent. The amount of asphalt blocks manufactured and laid as pavements has varied from 5,000 to 100,000 sq. yds. per annum, and the total from 1880 to 1890, inclusive, is estimated at 500,000 sq. yds.

About 55,000 sq. yds. of bituminous limestone pavement were laid in Washington, D. C., during 1876 and 1877, and about 3,000 sq. yds. in New York in 1883 or 1884. Nearly all of this was subsequently taken up and replaced by Trinidad asphaltum. In 1887 about 10,000 sq. yds. were laid in Rochester, N. Y.; in 1888 about 20,000 sq. yds. in St. Augustine, Fla.; and in 1890, 40,000 sq. yds. in New York City. Capt. F. V. Greene, of New York, estimates that the total amount of bituminous limestone pavement now in use in the United States does not exceed 75,000 sq. yds.

The asphalt pavements in Europe are all made from the bituminous limestones obtained from the localities mentioned previously in this report. The pavements are found in Berlin, London, Paris, and a few other cities, probably not exceeding ten in all. The total area covered is, approximately, as follows, and it is about one-fourth of that covered by Trinidad asphalt pavements in the United States: Berlin, 681,486 sq. yds.; London, 350,000 sq. yds.; Paris, 357,360 sq. yds.; other cities, 300,000 sq. yds.; total, 1,688,846 sq. yds.

Presence of Ethylbenzene in Commercial Xylene. E. Noetting and G. A. Palmar. *Ber.* 1891. **24**, 1955—1958.

The authors have isolated ethylbenzene from xylene by following the method devised by Friedel and Crafts for the purpose of separating ethylbenzene and the three xylenes which are formed together with other products by the action of aluminium chloride on toluene. The method is based on the fact that bromine in the presence of iodine converts all the xylenes completely into tetrabromo-derivatives, sparingly soluble in light petroleum and ethylbenzene into a readily soluble dibromo-derivative, which is subsequently converted into pentabromomethylbenzene by the action of bromine in presence of aluminium chloride. Since commercial xylene contains ethylbenzene, commercial xylidine should contain amidioethylbenzene, and the authors have also prepared pentabromomethylbenzene from commercial xylidine by separating the metaxylidine with glacial acetic acid, converting the product contained in the mother-liquor into monobromoxylene, according to Sandmeyer's method, and subjecting the latter to the above-described treatment. A number of samples of xylene and xylidine were examined, all of which were found to contain

ethylbenzene. As the latter boils a few degrees below xylene, the greater portion may be removed by concentrating the same by fractional distillation.—D. B.

Distillation of Coal Tar. Windmann. *Jour. f. Gasbeleuchtung*, 1891. **34**, 434—436.

The author describes the distillation of coal tar as conducted at the Pasing works in Bavaria. The distillation is effected in large wrought iron stills, heated by means of a furnace placed beneath the still. At the commencement a gentle heat is applied, and the distillation performed at the ordinary pressure, the water in the condensing apparatus being kept cold. The distillate consists of light oil and water. After all the water has come over, the heat is gradually increased, the atmospheric pressure diminished, and the temperature of the water in the condenser raised, the products of distillation being medium oil, heavy oil and anthracene oil. The distillation at the stage at which the latter comes over is aided by the injection of steam and the application of an exhausting air pump. The residue of distillation is pitch, which last product is run out from the bottom of the still. The products are worked up in the following manner:—The light oils having a specific gravity below 1.0, and consisting of benzene and its homologues, phenol, pyridine, and naphthalene, are subjected to fractional distillation. The crude benzene thus obtained is, in the first place, washed with a weak solution of caustic soda in order to remove all phenols, then treated with dilute sulphuric acid, which extracts the pyridine bases, and finally washed with concentrated sulphuric acid, which separates all tarry substances. The product is then subjected to distillation by means of steam, the following fractions being obtained:—

Benzene I.—Boiling from 80° to 100°, used in the preparation of aniline.

Benzene III.—Boiling from 100° to 120°, } used in the
Benzene IV.—Boiling from 110° to 140°, }

preparation of toluene, xylene, &c.

Benzene VI.—Boiling from 140° to 175°, } used in the
Benzene VII.—Boiling from 175° to 195°, }

manufacture of india-rubber.

The residue is added to and worked up with the medium oils. The soda solution partially charged with phenols is completely saturated therewith by mixing it with oil rich in phenols, separating the solution from the undissolved oily portion and decomposing by means of an acid. Crude carboic acid is thus obtained, and this is subsequently worked up into the pure crystallised acid. The acid solution charged with pyridine is neutralised with ammonia, and the crude pyridine thus liberated is subjected to fractional distillation. The product is now largely used for the denaturation of alcohol. The tarry acid liquor, after being washed with water and neutralised, yields a further portion of crude benzene on distillation, the residue being employed for fuel purposes. The medium oil, having a specific gravity of about 1.0, is subjected to fractional distillation. The first distillate represents crude naphtha, and is worked up with the light oil. The second distillate contains naphthalene and phenol. The former crystallises out on cooling, and is separated by draining the oil and subjecting the residue to hydraulic pressure. The drained oil is then submitted to fractional distillation, the first portions, which are highly charged with phenol, being used for the preparation of carboic acid, whilst the higher boiling fractions are employed as creosote oils. The heavy oils, having a specific gravity of about 1.0, contain phenol, naphthalene, and neutral oils. On re-distillation, an oil highly charged with naphthalene is obtained, the lower boiling fractions of which contain large quantities of phenol. This oil is worked up like the second oil obtained by the re-distillation of the medium oil. On cooling, the last product of distillation of coal tar, anthracene, mixed with other high-boiling hydrocarbons, crystallises out. This is collected in filter-presses, and the mass subjected to hydraulic pressure. The filtered oil is re-distilled, the first fractions being added to the creosote oils, whilst from

the higher boiling portions a further quantity of crude anthracene is obtained, which, is, however, inferior in quality and percentage strength to the anthracene separated from the original oil. The water which comes over with the light oil in the early part of the distillation being saturated with ammonia is converted into ammonium sulphate along with the gas liquor separated from the tar before it is submitted to distillation.—D. B.

IV.—COLOURING MATTERS AND DYES.

Euxanthone. J. Herzig. Monatsh. Chem. 1891, 12, 161—171.

WHILST engaged in his researches in the quercetin group (this Journal, 1889, 770), the author noticed some analogy between the properties of this group and euxanthone, and this investigation was therefore undertaken with the view to more clearly establish the relationship.

A striking similarity between the two substances is seen when they are converted into their acetyl-derivatives, the yellow colour disappearing in both cases whilst colourless substances are obtained.

Acetylexanthone, $C_{13}H_6O_2(C_2H_3O)_2$, crystallises from glacial acetic acid in pure white crystals, melting at 183° — 185° (uncor.). It can be hydrolysed by means of sulphuric acid in the same way as Liebermann hydrolysed acetyl-quercetin (Ber. 17, 1680).

Monethyleuxanthone, $C_{13}H_6O_3(OC_2H_5)_2$, is obtained on heating euxanthone with alcohol, potassium hydroxide, and ethyl iodide, even when two or three times the theoretical quantity of the reagents are employed. It crystallises in long yellow needles, melting at 144° — 145° . It is absolutely insoluble in potash, although according to its constitution it must contain an hydroxyl group; with alcoholic potash it yields an insoluble potassium compound, which, however, is decomposed on the addition of water, and ethyleuxanthone is obtained. Its acetyl-derivative—

is sparingly soluble in absolute alcohol, from which it crystallises in long, white, lustrous needles, melting at 180° — 182° . It can be hydrolysed by sulphuric acid.

Diethyleuxanthone, $C_{13}H_6O_2(OC_2H_5)_2$, which has been previously described by Graebe and Ebrard (Ber. 15, 1678), is obtained when the monethyl-compound is dissolved in absolute alcohol and repeatedly treated with an equal weight of potash and the corresponding quantity of ethyl iodide; it crystallises in long white needles, melting at 126° .

When diethyleuxanthone is heated with alcoholic potash for four hours at 130° — 150° , and the product mixed with water and extracted with ether, the monethyleuxanthone already described is obtained. When, however, diethyleuxanthone is heated on a water-bath with 20 parts of concentrated sulphuric acid for three hours, and the product diluted with water, monethyleuxanthone is isomeric with the above is obtained. It crystallises from alcohol in white needles, melts at 223° — 225° , and is soluble in dilute potash solution.

The properties of the isomeric monethyl derivatives lead to the assumption that the two hydroxyl-groups in euxanthone are of a different nature, namely, that one is of an alcoholic, and the other of a phenolic character. By way of explanation the author suggests the following modification of the euxanthone formula—

but at the same time points out that this would probably be a very labile form, and that whilst euxanthone may possibly exist only in the more stable modification—

its alkyl-derivatives may exist in both forms.—A. K. M.

Quercetin and its Derivatives. VI. J. Herzig. Monatsh. Chem. 1891, 12, 172—176.

Molecular Weight of Quercetin.—In a previous communication (Monatsh. Chem. 9, 537), the author showed that the examination of the alkyl- and acetyl-derivatives of quercetin led to the number 292 as the simplest expression for the molecular weight of this substance. According to this result, Lowe's formula, $C_{15}H_{12}O_7$, is the only one of those which have been proposed which can be correct. From analytical data, as well as from some of its reactions, it would appear, however, that the formula is $C_{15}H_{10}O_7$ rather than $C_{15}H_{12}O_7$.

In the present paper the author describes experiments on the determination of the molecular weights of quercetin and acetylquercetin by Beckmann's method. The molecular weight found was 258 for quercetin, the calculated being 302; the numbers for acetylquercetin were 402, 450, and 416, the calculated molecular weight being 456. The analytical numbers previously obtained with quercetin and several of its derivatives also agree with the formula $C_{15}H_{10}O_7$. Assuming this to be correct, rhamnetin should be *monomethylquercetin* and not the dimethyl-derivative as was previously assumed by the author.

The investigation of fisetin (*see next abstract*) and the relationship which this bears to quercetin, also tend to support the view that the latter substance has the formula $C_{15}H_{10}O_5$.—A. K. M.

Quercetin and its Derivatives. VII. J. Herzig. Monatsh. Chem. 1891, 12, 177—190.

Fisetin.—The investigation of this substance was undertaken with the view to establish its composition and to clear up the discrepancies which are evident when the formula $C_{15}H_{10}O_6$ proposed by Schmid (this Journal, 1886, 450) is considered in connexion with the relationship which fisetin bears to quercetin.

Acetylfisetin was obtained in the form of lustrous white needles melting at 196° — 199° , and agreeing in composition with the formula $C_{15}H_8O_2(OC_2H_5O)_4$. On hydrolysis it yielded practically the theoretical amount of fisetin, and when this was analysed numbers were obtained agreeing with the formula $C_{15}H_{10}O_6$. The fact that acetylquercetin contains five acetyl-groups, whilst acetyl-fisetin contains only four, is in accordance with the view that quercetin is hydroxyfisetin.

Methylfisetin, $C_{15}H_{10}O_2(OCH_3)_4$. The author finds that in accordance with Schmid's results, the same number of hydroxyl-groups which are replaceable by acetyl can also be replaced by methoxyl. After very careful purification, the product is obtained in long white lustrous needles melting at 151° — 153° ; it is not yellow as stated by Schmid. In this property of losing its colour when completely acetylated or alkylated, fisetin resembles quercetin and euxanthone.

Ethylfisetin, $C_{15}H_{10}O_2(OC_2H_5)_4$, crystallises from alcohol in white lustrous needles melting at 106° — 108° .

These white compounds do not react with acetic anhydride and, therefore, do not contain any free hydroxyl-group.

When an alkaline solution of fisetin in potash is exposed for 24 hours to the air it becomes completely oxidised, protocatechuic acid and resorcinol being produced. This is analogous to the oxidation of quercetin, which, under similar conditions yields protocatechuic acid and phloroglucinol, and the reaction thus affords further evidence in favour of quercetin being a hydroxyfisetin.

When ethylfisetin is boiled with alcoholic potash for 7—8 hours it undergoes a quantitative decomposition into diethylprotocatechuic acid, and a substance having the

properties of a phenol, and which the author names *ethylfisetol*. This substance crystallises from alcohol in white needles, melting at 42—44°, and gives a pale red colouration with ferric chloride. Its formula is probably $C_{15}H_{10}O_6(OC_2H_5)_2$. When it is treated with ethyl iodide and potash it becomes ethylated, and the product, probably $C_{15}H_{10}O_6(OC_2H_5)_3$, is insoluble in potash and crystallises from dilute alcohol in long needles, melting at 66—68°. Ethylfisetol readily yields resorcinol on fusion with potash.

Alcoholic potash decomposes methylfisetin in the same way, dimethylprotocatechuic acid and methylfisetol being produced. Methylfisetol crystallises in small white needles, melting at 66—68°; its methyl-derivative, $C_{15}H_{10}O_6(OCH_3)_3$, also forms small white needles, and melts at 62—63°, whilst its ethyl-derivative, $C_{15}H_{10}O_6(OCH_2CH_3)_2(OC_2H_5)$, forms soft lustrous needles, melting at 60—62°.

From the above results the following equation may be taken to represent the decomposition which occurs when the alkyl derivatives of fisetin are treated with alcoholic potash:—

and since the four alkyl-groups of the alkyl-fisetin are all present in the two products, the conclusion is justified that the carboxyl-group in the protocatechuic acid and the free hydroxyl-group of the alkyl-fisetol have been formed by the addition of the elements of water. The constitution of fisetol is not yet determined; it is, however, a derivative of resorcinol, and contains a third hydroxyl-group, which, it is thought, must be present in a side-chain; the fourth oxygen atom appears to belong to an aldehyde- or ketone-group, as a phenylhydrazine-derivative has been obtained.

—A. K. M.

Methylation of Symmetrical Orcinol. A. Kraus. Monatsh. Chem. 1891, 12, 191—204.

Zeisler and Herzig have shown that in the product of the action of alkyl iodide and potash on phloroglucinol, the alkyl groups are directly attached to the carbon atoms of the nucleus, and are not present as alkoxy (Monatsh. Chem. 1889, 114). They also showed that in the ethylation of resorcinol, part of the ethyl introduced became directly attached to carbon, whilst part replaced hydroxylic hydrogen (Monatsh. Chem. 1890, 291). In continuation of these experiments the author has treated orcinol with methyl iodide and potash, and has obtained the following products:—1. A crystalline dimethylresorcinol which melts at 204°, and which is soluble in alkali; a methoxyl determination showed that neither methyl group was present in the form of methoxyl. The oily mother-liquor from this, which was soluble in alkali, was further methylated and treated with potash, and when the soluble portion was fractionated under diminished pressure it became insoluble in potash. These products contained no methoxyl. 2. A crystalline tetramethylresorcinol melting at 93—94°; this contained two methoxyl groups, and its formula is consequently—

3. A dimethyl derivative, $C_6H_4(CH_3)_2(OC_2H_5)_2$, containing two methoxyl groups, and which was separated by means of its dibromo-compound.

The oily mother-liquor from $C_6H_2(CH_3)_4(OCH_3)_2$, which was insoluble in alkali, and consequently contained no hydroxyl group, was treated with hydrogen iodide, when a product was obtained which melted at 156°. This proved to be a dimethylresorcinol isomeric with the one described above, and which melts at 204°. The author assigns the following formulae to these two substances:—

Melting point 156°.

Melting point 204°.

—A. K. M.

Gentisin. S. v. Kostanecki. Monatsh. Chem. 1891, 12, 205—210.

GENTISIN was first prepared by Henry and Caventou, from gentian root, and was believed by them to be the bitter principle of the root (J. de Pharm. 1821, 178). Trommsdorff subsequently showed that this was not the case, and stated that gentisin is a yellow, crystalline, and tasteless substance (Ann. 21, 134). Its composition was shown by Baumert to be $C_{15}H_{10}O_5$ (Ann. 62, 106), and this was confirmed by Hlasiwetz and Habermann (Ann. 175, 63; 180, 343), who further showed that it contained two hydroxyl groups and a methyl-group, and that on fusion with potash it yielded phloroglucinol and quinolearboxylic acid; they eliminated the methyl-group by heating gentisin in a current of hydrogen chloride, but assumed that it was directly united to carbon, and they did not examine the product.

The author has demethylated gentisin by Zeisel's method, and has obtained a substance of the composition $C_{15}H_8O_5$, which he names *gentisein*, and which may possibly prove to be trihydroxyanthone. Gentisein crystallises from very dilute alcohol in groups of small needles of a straw-yellow colour, and containing two molecules of water of crystallisation. The colour becomes more pronounced when the water is driven off either by heat or by placing the substance in a desiccator. It melts at 315°, yields a pure yellow solution with alkali, and a blood-red colouration with sodium amalgam. When gentisein is boiled with acetic anhydride and sodium acetate, it yields a triacetyl-derivative—

which crystallises in beautiful white needles melting at 226°. Since gentisin yields only a diacetyl-derivative, it follows that the methyl-group which it contains must be present in the form of methoxyl, and not directly attached to the carbon, as assumed by Hlasiwetz and Habermann.

A reaction which distinguishes gentisein from gentisin is that the latter, although it yields yellow solutions, will not dye mordanted cotton, whilst gentisein gives bright yellow shades. It is assumed that this property of gentisein is due to the hydroxyl-group, the hydrogen of which is replaced by methyl in the gentisin.—A. K. M.

On Gentisin. St. v. Kostanecki and E. Schmidt. Monatsh. Chem. 1891, 12, 318—322.

ONE of the authors has described in a previous communication (preceding abstract) a substance (gentisein) which is obtained by splitting off a methyl-group from gentisin. In the belief that gentisin is a methyl-ether of gentesein, they have endeavoured to introduce methyl groups in both these bodies, in the hope that both would give rise to the same gentisein-tri-methyl-ether. Experiment shows that they do give the same end-product, thereby confirming the view that the one is a mono-methyl-ether of the other, since this end-product turns out to be not the tri-methyl but the di-methyl ether of gentisein.

Gentisin-di-methyl-ether (Gentisin-mono-methyl-ether)—

This is prepared as follows:—One molecule of gentisin is heated some hours in a tube at 100° with two molecules of caustic potash and two molecules of methyl iodide, in solution with methyl alcohol. The result is a yellow crystalline mass, which is treated with dilute caustic soda, to dissolve out unattacked gentisin. The major part remains undissolved, and, after treatment with dilute HCl, remains as a yellow mass. This crystallises from acetic acid in broad yellow needles, which melt at 170°, and is the mono-methyl-ether of gentisin. The characteristic property of this substance is that its alkali-salts are only soluble in water with great difficulty. This behaviour is opposed to the idea that gentisin is a xanthone derivative. Almost insoluble alkali salts of the oxy-xanthon are mentioned by Michael.

Acetyl-gentisein-dimethyl-ether—

This is prepared by the aid of acetic anhydride and dehydrated sodium acetate. The acetyl product thus obtained is crystallised from alcohol; melting point, 189° .

The results obtained by Hlasiwetz and Habermann on melting gentisein with caustic potash, give us some idea as to what the position of the three hydroxyl groups in this body may be. For as they obtained phloroglucinol and quinol-carbonic acid, gentisein would appear to have the following formula:—

However plausible this constitution formula may appear, there are strong objections to it. In particular, gentisein dyes mordanted wool, and should therefore have two hydroxyl groups in the ortho position, which is not the case according to their formula. There is little to support the supposition that the rule which holds good for the phenol colours does not hold good for the hydroxy-xanthone ones; in fact the author finds that all hydroxy-xanthones which do not contain two hydroxyl groups in the ortho position do not dye mordanted wool. This is also true for the oxyketones prepared by Nencki and his pupils. Tobel has also shown that even the hydroxy-cumarines in which the chromophore, CO, is not directly connected to the benzene-ring, behave in the same way; they act as fast dyes when they contain two hydroxyl groups in the ortho position.

It is rather remarkable that the colouring powers of the hydroxy-ketones and hydroxy-cumarines have been overlooked until recently. The explanation is that many of them are completely colourless, and it has long been a doubtful question whether a single ketone-group could act as a chromophore. This question can now be easily decided, for if the substance under investigation be converted into its orthodihydroxy-derivative, it can easily be decided whether that substance can play the part of a chromogen or not.

—D. E. J.

The Synthesis of Oxyxanthones. St. von Kostanecki and B. Nessler. Ber. 1891, 24, 1894—1897.

THE authors were led to a general method of preparing oxyxanthones by the observation that both orsellinic and parorsellinic acids on distillation with salicylic acid and acetic anhydride yielded the same oxymethylxanthone, identical with the salicyorein ether of Michael. (Amer. Chem. J. 1883, 5, 95.) But the reaction really furnishes two isomeric oxymethylxanthones.

α-oxymethylxanthone melts at 140° , forms a characteristic, difficultly soluble, yellow sodium salt, and yields an acetyl derivative crystallising in white needles having a melting point of 152° .

β-oxymethylxanthone, $C_{13}H_{16}O_5(OH)(CH_3)$ crystallises in colourless needles melting at 285° and dissolving easily in alkaline solutions with a yellow colour.

The distillation of resorcinol with salicylic acid and acetic anhydride yielded a similar substance, of which the chief part was identical with the *m*-oxyxanthone of Michael. By uniting phloroglucinol with salicylic acid, the author obtained a new isoxanthone, $C_{13}H_{16}O_5(OH)_2$ [1:3], crystallising in needles of light yellow colour, melting at 247° , and dissolving in alkalis with a yellow colour.

—G. H. B.

Benzidine Dyes. R. Brach and G. Freyss. Ber. 1891, 24, 1958—1966.

It is known that whilst ortho-derivatives of benzidine, such as orthotolidine and orthodianisidine, yield substantive

cotton dyes, meta-derivatives give dyes suitable only for wool. The bases—

yield dyes which have but little affinity for the fibre (Noelting and Strieker, this Journal, 1889, 114), and the base—

(diazotised and combined with *α*-naphthol-*α*-sulphonic acid) yields a dye similar in its properties to benzazurin; and the corresponding tetrabenzyl compound also gives dyes which attach themselves readily to the fibre (Colson, this Journal, 1889, 451). The author finds that the base—

yields dyes which show scarcely any affinity for vegetable fibre.

In order to prepare this base, a solution of paratolidine nitrate is treated cold with nitric acid and sodium nitrite, the resulting diazo-compound is heated, and thereby converted into metanitroparacresol; this is then methylated and the resulting methylnitroresol dissolved in methyl alcohol and heated with sodium methylate. The azoxy-product obtained crystallises in yellow prisms, melts at 148° — 149° , and is readily soluble in benzene, glacial acetic acid, and alcohol.

Dimethyl azoparacresol—

is obtained by the action of sodium amalgam or a solution of methyl metanitroresol, and crystallizes in large well-formed scarlet prisms melting at 178° — 179° ; it is sparingly soluble in alcohol, readily in glacial acetic acid, in chloroform, and in benzene. If a large excess of sodium amalgam be employed, the reduction goes further, and the base $C_6H_3(OC_2H_5)(NH_2)(CH_3)$ [1:2:4] is obtained. When this is diazotised and the diazo-compound combined with paracresol, methyl azoparacresol is produced, and this on methylation yields the above dimethyl azoparacresol. The conversion of this into the base sought for is effected by adding a solution of stannous chloride to the hot hydrochloric acid solution of the azo-compound. The pure base forms silvery scales melting at 156° — 157° ; it dissolves readily in alcohol, sparingly in water.

Diazotised orthodimethoxymetadimethylbenzidine combined with *R*-salt yields a reddish-violet colour, which dyes unmordanted cotton a light violet and wool and silk a fine violet-red. The red dye obtained with *α*-naphthol-*α*-sulphonic acid dyes wool and silk red and gives a pale pink on unmordanted cotton. The diazotised base yields a yellowish red dye with *α*-naphthylamine-*α*-sulphonic acid and a pure yellow dye with salicylic acid; this readily dyes wool and silk in an acid bath, but scarcely colours cotton.

—A. K. M.

Orthonitrotoluenes. E. Strong. Ber. 1891, 24, 1987.

Para- orthonitrotoluene boils at 218°, and not at 223° as usually stated; it solidifies completely at -10.5°; its specific gravity at 15° is 1.168.—A. K. M.

Synthesis of Indigo-sulphonic Acids (Indigo-carmines). R. Knietsch. Ber. 1891, 24, 2086—2089.

According to the author, Heymann's explanation of the synthetic formation of Indigo-carmines is incorrect (this Journal, 1891, 829). The synthesis takes place in two stages, and is analogous to Heymann's synthesis of indigo (this Journal, 1890, 1121). In the first stage of the reaction the fuming sulphuric acid abstracts the elements of water, and a leuco-compound is produced, and this becomes sulphonated. The second stage consists in the conversion of the leuco-compound into indigo-sulphonic acid by the action of atmospheric oxygen. The leuco-compound is very unstable in acid solution, and if left for a few hours at the ordinary temperature it is no longer capable of yielding indigo; its oxidation to Indigo-carmines only takes place when the excess of sulphuric anhydride is removed by dilution. According to Heymann the sulphuric anhydride acts as an oxidising agent, but the author states that this is not the case, and that the amount of sulphur dioxide is not greater than is usually the case in such reactions.

—A. K. M.

Isolation of Aromatic Sulphonic Acids. L. Gattermann. Ber. 1891, 24, 2121—2122.

The isolation of aromatic sulphonic acids from the mixed sulphonation product is generally effected by the addition of barium, calcium, or lead salts. The same result may be obtained with greater facility by saturating the sulphonation product dissolved in twice its volume of water with common salt. The resulting sodium salts are in most cases thrown out in well-crystallised forms, and the yield is frequently quantitative. The author has isolated in this manner the sulphonic acids of benzene, toluene, xylene, and mesitylene, also phenol-*p*-sulphonic acid, and metasulphobenzoic acid. —D. B.

Hydroxy-azo (Oxy-azo) Compounds. H. Goldschmidt and E. Brubacher. Ber. 1891, 24, 2300—2317.

The object of the experiments described in this paper was to decide whether the so-called hydroxy-azo compounds are really such, or whether they are hydrazones of the quinones (compare also this Journal, 1890, 191). From the results obtained, the authors have decided in favour of the hydrazone formula.

I. *Orthohydroxyazo-Compounds.*—The acetyl-derivative of benzene-azo-*para*-resol was obtained by boiling the latter with acetic anhydride; it melts at 87°—88°, not at 67°—68° as usually stated. When an alcoholic solution of this acetyl-derivative is treated with zinc dust and a little dilute acetic or formic acid, reduction takes place, and acetanilide and amidopara-resol ($\text{CH}_3\text{NH}_2\cdot\text{OH}$ 1:3:1) are obtained.

II. *Parahydroxyazo Compounds.*—The acetyl- and benzoyl-derivatives of these give hydrazone-compounds on reduction with zinc dust and acetic acid.—A. K. M.

On the Tetrazo Dyes. P. Werner. Monit. Scient. 1891, 5, 601—609.

The present paper forms the last of a series of articles (Monit. Scient. 1891, 22, 135, and 182) in which the author discusses the formation of various tetrazo dyes. The following conclusions were arrived at:—

In order that a tetrazo colouring body may act as an efficient substantive dye, it is essential that the two amido-groups be symmetrically disposed. The derivatives of

diphenylene and ditolylene, for instance, possess scarcely any direct dyeing action. On the other hand, the colouring matter itself need not be symmetrically constituted. This is exemplified by Cassella's oxydiphenyl dyes, and the derivatives of benzidine-monosulphonic acid. As regards the benzidine series of dyes, the removal by substitution of a hydrogen atom occupying the meta position in respect to the amido-group, results in a decrease of tinctorial power. The latter is again increased, however, by the substitution of methyl for the ortho-hydrogen atom.

Diphenylene substituted in both meta positions (reckoning from the amido-groups) yields dyes which are practically valueless, owing to their feeble direct action on the fibre. This is probably so because, by the substitution of the two meta positions, the attraction between the benzene nuclei is diminished. The bases in which the meta positions are connected by means of a divalent atom or radicle, such as S_2O , CH_2 , or SO_2 , yield substantive dyes; whilst bases in which the meta hydrogen atoms are replaced by monovalent atoms or radicles (Cl, Br, &c.) yield substances resembling the corresponding benzene derivatives. The above rule only applies to the diphenylene series of dyes. It does not hold good, for instance, in the case of the derivatives of diamidostilbene, the tinctorial power of which is unaltered by substitution of the meta hydrogen atoms. The tetrazo colouring bodies obtained from the more complex bases in which the benzene nuclei are separated by one or more other groups, may be divided into two classes—substantive dyes and dyes possessing no affinity for vegetable fibres; and it would appear that a species of condensation occurs between the benzene rings to which the amido-groups are attached, which determines this difference in behaviour. For example, the tetrazo derivatives of diamidodiphenyl, triphenylmethane, diamidosulphobenzide, and diamidodibenzyl have no dyeing action; whilst the colours obtained from diamidofluorene, diamidobenzophenone, diamidodiphenylacetone, benzidine sulphonic acid, diamidotoluene, and diamidostilbene dye cotton without the aid of a mordant. The theory does not explain, however, why the derivatives of ethylenediparaamidophenol—

act as dyes, whilst those of diamidodibenzyl—

do not.—H. T. P.

PATENTS.

Improvements in the Production of Blue Colouring Matters. D. Dawson, Milnsbridge. Eng. Pat. 17,195, October 28, 1890, 6d.

A process for obtaining colouring matters by the action of a salt of dimethylaniline on diphenylamine, benzil-diphenylamine, methyl- or ethyl-diphenylamine in presence of salt and copper sulphate, phenol being used as a diluent. The melt is stirred for several hours at 95°–100° C., or the reaction may be allowed to take place in the cold, but a much longer period is necessary for completion. In place of copper sulphate, potassium ferricyanide may be employed, but in this case a large quantity of the latter is required, and the melt must be kept at 100° C. for two days. The subsequent treatment is in both cases the same. The melt is washed first with cold water, and afterwards with hot water containing acid. After purification the colouring matters may be employed for dyeing in the same way as the "spirit blues" from rosaniline, or they may be sulphonated giving wool dyestuffs. Other colouring matters are obtained by passing bromine or chlorine into dimethylaniline hydrochloride, mixing the product with diphenylamine and heating the mixture until no more colour is formed. The dyestuff is then purified as above.—T. A. L.

The Manufacture and Production of New Derivatives of Alizarine or its Analogues. B. Willeox, London. From the "Farbenfabriken vormals F. Bayer und Co.," Elberfeld, Germany. Eng. Pat. 17,712, November 4, 1890. 6d.

THIS is an extension of Eng. Pats. 8725 and 12,715 of 1890 (this Journal, 1891, 537 and 739). The methods employed for producing "Bordeaux" from the di- and tri-hydroxy-anthraquinones there described also yield colouring matters when applied to quinizarin and xanthopurpurin according to the present application. Moreover the purpurin Bordeaux described in the first named patent may, on oxidation with manganese dioxide in a sulphuric acid solution be converted into a Cyanin identical with that derived from alizarin. It has also been discovered that these oxidations may be performed by means of sulphuric acid or sulphuric anhydride, the products obtained resembling the Cyanins very closely. The following process describes the production of a Bordeaux and its oxidation in one operation. About 10 kilos. of dry purpurin are stirred into 150 kilos. of fuming sulphuric acid containing 80 per cent. of anhydride. The mixture is allowed to stand for some time at a temperature not exceeding 50° C., until a sample precipitated by water, dissolved in soda, decomposed with an acid and dried, dissolves in alkalis or concentrated sulphuric acid with a violet colour, and shows a strong fluorescence. The melt is subsequently treated in a manner similar to that described in Eng. Pat. 8725. The product obtained is a hexa-hydroxy-anthraquinone. In the formation of the cyanins from the bordeaux, intermediate compounds are formed, which yield valuable dyestuffs when treated with ammonia. A series of colouring matters similar to the cyanins are obtained by oxidising with sulphuric acid and manganese dioxide, the dyestuffs described in Eng. Pat. 12,715, produced by the action of ammonia on the bordeaux intermediate products of alizarin purpurin, flavo- and anthra-purpurin. All these colouring matters dye mordanted wool blue, greenish-blue, or violet-blue shades according to the particular dyestuff and mordant employed.—T. A. L.

Improvements in the Manufacture of Colouring Matters. H. H. Lake, London. From A. Leonhardt and Co., Mühlheim-on-the-Maine, Germany. Eng. Pat. 18,623, November 18, 1890. 6d.

THE greenish-blue dyestuffs described in Eng. Pat. 13,565 of 1890 (this Journal, 1891, 760), can also be obtained according to the following methods:—

(1.) By oxidising a mixture of dimethyl-*m*-amidocresol with an aromatic *p*-diamine (preferably *p*-phenylene diamine or *p*-amido-dimethylaniline). Instead of using ordinary oxidising agents such as bichromates, manganese dioxide with acetic acid or ferric chloride, the oxidation can be effected by means of amido-azo-compounds; in this case the azo-dyestuff (such as amido-azo-benzene or benzene-azo-di-methylaniline) is heated with the amido-cresol preferably in a glycerol or phenol solution.

(2.) Nitroso-dimethylaniline hydrochloride when condensed with dimethyl-*m*-amidophenol yields a greyish-blue dyestuff consisting of a mixture of a grey and a blue colouring matter. These two products can be separated either by fractional precipitation with salt and zinc chloride or with sodium acetate or carbonate. The grey product under these conditions is first precipitated.

(3.) Di-alkylated nitroso-*m*-amidophenols do not form blue dyestuffs when condensed with aniline or dimethylaniline. They are, however, obtained from a salt of nitroso-dimethyl or diethyl-*m*-amidophenol when condensed with *m*-toluylene diamine, *m*-amidodimethylaniline or *m*-amidodiethyl-*o*-toluidine. The condensation is performed by heating the components in a dissolving or "distributing" medium, such as spirit or acetic acid, and the dyestuff is purified as described above.—T. A. L.

The Manufacture of New Derivatives of Anthraquinone. B. Willeox, London. From the "Farbenfabriken vormals F. Bayer und Co.," Elberfeld, Germany. Eng. Pat. 18,729, November 19, 1890. 6d.

THE processes for obtaining dyestuffs from alizarin and its analogues according to Eng. Pats. 8725, 12,715, and 17,712 of 1890 (see above), can be applied according to this patent to oxyflavopurpurin and oxyanthrapurpurin, substances which are obtained by the action of oxidising agents on flavo- and anthrapurpurin in presence of concentrated sulphuric acid. These bodies are also dyestuffs, and give much bluer shades than the original compounds. The methods for producing the Bordeaux previously described have also been applied to anthrarufin, which does not itself possess colouring properties. Furthermore, the hexahydroxyanthraquinone described in Eng. Pat. 17,712 of 1890 can be obtained directly from anthraquinone by the action of pure sulphuric anhydride at a temperature not exceeding 50° C.

T. A. L.

The Production of Sulphonated Thionines and Dyestuffs therefrom. S. Pitt, Sutton. From I. Cassella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 19,065, November 24, 1890. 4d.

AN extension of Eng. Pat. 4596 of 1890 (this Journal, 1891, 357). Blue colouring matters are obtained by oxidising ethyl- or methylsulphobenzyl-*p*-phenylenediamine sulphonic acid together with certain naphthalene derivatives. The following derivatives are mentioned:—*α*-naphthylamine, methyl-*α*-naphthylamine, 1:2-naphthylamine sulphonic acid, *α*-naphthol, *α*-naphthoic acid, and 1:2-*α*-naphthol-sulphonic acid. A colouring matter dyeing wool a deep blue is obtained as follows:—A solution containing 42 kilos. of the thiosulphonic acid mentioned above, and 18 kilos. of *α*-naphthylamine hydrochloride is treated with a solution of 30 kilos. of potassium bichromate and 100 kilos. of a concentrated solution of zinc chloride. A dark green-coloured indamine separates, and the whole solution is heated for an hour to 100° C., when the thionine is obtained in the form of its insoluble chromium lake. The dyestuff is extracted by sodium carbonate or acids, and being only sparingly soluble in water, requires sulphonation for use as a colouring matter.—T. A. L.

The Preparation of Colouring Matters with Gamma-amidonaphtholsulphonic Acid. S. Pitt, Sutton. From I. Cassella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 19,330, November 27, 1890. 6d.

AN extension of Eng. Pat. 16,699 of 1889 (this Journal, 1890, 935). One molecular proportion of diazotised benzidine or other *p*-diamine is combined with one molecular proportion of *γ*-amidonaphthol sulphonic acid in an alkaline solution. The resulting compound is then diazotised and combined with two molecular proportions of *γ*-amidonaphthol sulphonic acid. The dyestuff separates as a black precipitate, and gives black shades on unmordanted cotton fast to light and washing. Similar dyestuffs result by using one molecular proportion of *α*-naphthylamine in the first stage of the above process (Eng. Pat. 9214 of 1885; this Journal, 1889, 701). Another modification of the process is to combine equal molecular proportions of a diazotised *p*-diamine and *γ*-amidonaphthol sulphonic acid, re-diazotise, and combine with two molecular proportions of an amine or phenol or their sulphonic acids.—T. A. L.

Improvements in the Manufacture of Colouring Matters. H. H. Lake, London. From Kalle and Co., Biebrich-on-the-Rhine, Germany. Eng. Pat. 20,845, December 20, 1890. 6d.

THE Rosinduline described in Eng. Pat. 15,259 of 1888 (this Journal, 1889, 877) has been found to belong to a new class of basic colouring matters of the general formula $C_{22}H_{11}N_3R$, which on sulphonation yield valuable dyestuffs. The Rosinduline $C_{22}H_{11}N_3$ is prepared by heating a salt of

benzene-azo- α -naphthylamine with aniline in presence of alcohol. It crystallises in reddish-brown plates melting at 199° C. The Rosindulines $C_{22}H_{19}N$ and $C_{22}H_{19}N_2$ are prepared by heating the chlorhydrates of benzene-azo- α -tolyl- α -naphthylamine or benzene-azo-di- α -naphthylamine with aniline at 130–150° C. The two bases obtained crystallise in reddish-brown plates and melt at 228 and 256° C. respectively. The Rosinduline obtained from aniline and benzene-azo- α -tolyl- α -naphthylamine melts at 233°. The salts of all these compounds dye mordanted cotton. To prepare the sulphonic acids, 1 part by weight of the base is dissolved in 4 parts of sulphuric acid containing 24 per cent. of SO_3 , and the mixture heated for 4–5 hours at 80° C. The melt is then poured into water, filtered, dissolved in ammonia, and the solution evaporated to dryness.—T. A. L.

Improvements in the Manufacture of a New Amidonaphtholsulphonic Acid and Colouring Matters therefrom. S. Pitt, Sutton. From L. Cassella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 1742, January 30, 1891. 6d.

THE new acid is obtained from α -diamidonaphthalene disulphonic acid of Eng. Pat. 15,316 of 1890 (this Journal, 1891, 761) by heating it with dilute mineral acids, when one amido group is replaced by a hydroxy group according to the following equation:—

The new amidonaphtholsulphonic acid is termed "acid H." It combines with diazo- or tetrazo-compounds, and with diazotised benzidine gives a colouring matter which dyes unmordanted cotton a pure blue. A bluish-black dyestuff for unmordanted cotton is obtained by combining 21 kilos. of diazotised toline with an alkaline solution of 32 kilos. of the "acid H." The intermediate compound thus formed is combined with 27 kilos. of γ -amidonaphthol sulphonic acid, and the whole allowed to stand for 48 hours at 15° C. The action of nitrous acid on the acid itself forms a diazo compound which separates in fine yellow needles and turns violet by the action of alkalis.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

PATENTS.

Improvements in the Method of and Means for Removing Grease and Fatty Matters from Textile Fabrics. T. J. Hutchinson, Manchester. Eng. Pat. 10,285, July 3, 1890. 8d.

THIS invention consists of a continuous process of passing the fabric through a suitable volatile solvent contained in a tank or series of tanks, within a closed chamber, the tanks being so arranged that between each tank and the next and at the end of the last tank there is a pair of squeezing rollers. Leaving these, the fabric is passed over a series of drying rollers (within a second chamber), heated by steam or otherwise, and the vapours rising from this chamber are condensed and employed over again for cleansing, together with the whole of the remaining liquid, which is allowed to flow from one tank to the other, and is then distilled for use again.—H. S.

Improvements connected with the Mixing of Natural or Artificially Short-staple Vegetable Fibres, so that they will Spin more Easily than when Spun together Unprepared. K. T. Sutherland and G. Esdaile, Manchester. Eng. Pat. 12,643, August 1, 1890. 1d.

THIS is an application of the inventors' previous patents, Eng. Pats. 15,333 and 18,932 of 1889 (see this Journal,

1890, 856 and 1033), for the purpose of mixing natural or artificially short-staple vegetable fibres, e.g., vegetable silk, cotton, china-grass, &c.

The claims are: (1.) "That yarn, thread, or strand spun from partly or wholly prepared fibres will be stronger than that spun from unprepared fibres, and be more useful." (2.) "That it will allow of different fibres in combination being spun on a commercial scale successfully." (3.) "That cloth woven from such yarn will be better, and can be applied to new purposes."—H. S.

Improvements in Rendering Canvas and other Fabrics Rot-proof. J. Williams, London. Eng. Pat. 12,513, August 11, 1890. 4d.

See under XIII., page 937.

Improved Treatment of Long-staple Stalk-Fibres as China-Grass, Flax, and such like Fibres, by which they will have a more even Staple when Artificially Shortened. K. T. Sutherland and G. Esdaile, Manchester. Eng. Pat. 13,965, September 5, 1890. 4d.

THIS invention refers to the treatment of stalks when gathered and denuded of their leaves in either of the following ways. The fibre is stripped from the stalk, and while moist and supple straightened out and pressed into bales. Or, the stalks are baled with the fibre on. Both are then cut into the requisite lengths necessary for working on cotton or woollen machinery by any effective cutting machine. A more even staple is thus obtained than from the dry article.—H. S.

Improved Process for the Production of Dyed Cotton Yarns or Threads. T. Salzmann, Vorarlberg, Austria. Eng. Pat. 17,872, November 6, 1890. 4d.

COTTON roving or twisted sliver in the form of hanks is bleached, dyed, and then spun and doubled to produce yarns or threads of uniform colour or of shaded or mixed colours.—E. B.

Improvements in and connected with Carbonisers, applicable for the Destruction of Vegetable Matter mixed with Wool, and for other Purposes. B. Bellerstein, Neuss, Germany. Eng. Pat. 13,722, January 24, 1891. 6d.

FOR this invention there is employed a drum, revolving on hollow trunnions and containing the material to be carbonised. Through the hollow trunnions carbonising gases (sulphuric or muriatic acid, &c.) are led into the drum after they have been superheated by means of a special heating chamber. Owing to the high temperature the gases or vapours act on the raw material more vigorously and rapidly than usual.—H. S.

Improvements in Cleansing Wool and similar Materials. A. George, Puteaux, France. Eng. Pat. 6663, April 17, 1891. Under Internat. Conv. October 31, 1891. 4d.

THIS process is based upon the fact that, while the fatty or waxy matters, or such as are soluble in water, or the sandy and earthy ingredients in wool and similar materials can be removed by the ordinary cleansing method, the pitchy and glutinous matters, insoluble in the usual solvents, remain. The wool is therefore subjected to the effects of gases by which these deleterious substances are decomposed; owing to its not injuring either the wool or the fatty substances, carbonic acid gas is claimed as being the most suitable.

The wool is subjected to this treatment either before or at the same time as it is treated with the solvents, and does not undergo "any injurious wear and tear, or alteration in its nature."—H. S.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Researches on the Formation of Pigment Lakes.

C. O. Weber.

See pages 896—902.

The Treatment of Leather for Dyeing and Colouring Purposes. E. M. Shaw. J. Soc. Dyers and Colourists, November 15, 1891.

HAVING glanced over the formation of skin, the author next considers the methods usually adopted to divide and remove such portions as are known to be useless for the production of suitable leather for the purpose of dyeing and colouring. These portions comprise the whole of the cuticle, including the malpighi network, with the hair or wool, with their roots, and an albuminoid fluid cementing together the fibrous tissue of the corium, and known as coriin.

The removal of the cuticle is effected by macerating the skin for some time in water, whereby the mucous layer dividing the malpighi net and the grain is dissolved, thus rendering the epidermis loose, which then speedily separates, carrying with it the hair.

It is found in practice that this result may be attained much quicker by the aid of alkali added to the water. Various alkaline salts have been proposed and tried with more or less satisfactory results, but the one generally used, either alone or in conjunction with some other, is lime. For our purpose of dyeing it is found that a skin receiving careful attention in the lime solutions is better for having a prolonged stay than a too short one. Of course it may be allowed to remain far too long, and will then be rendered useless, but a definite stay is necessary for the removal of the coriin. This is an albuminoid fluid binding together the fibres of the coriin, and supplying also the fluid to the cells of the cuticle. It is insoluble in water, but soluble in alkaline solutions or strong hydrochloric acid. It is precipitated from an alkaline solution by adding a small quantity of acid. Advantage is taken of lime for the removal of coriin, and to accomplish that end the skins are placed in large tanks or pits filled with water, and into which a large excess of lime has been thrown. The use of a more caustic alkali has often been suggested, but there is always the danger of partially or wholly destroying the papille, or grain of the skin, by their use.

Lime also swells or plumps the skin to a great extent, which is advantageous for some purposes, while for others no advantage may be claimed.

When the skin is considered to have had sufficient lime it is bated, as a means to entirely remove the coriin remaining.

Bating is a most disagreeable and nauseous process, and is still the subject of a great amount of research to discover why certain results are obtained by this means which other processes have so far failed to give.

Bating is accomplished by the use of certain animal dung. A bath is prepared containing the required quantity, partly in suspension and partly in solution, in water at about 90° F. In this the skins are placed after liming, and macerated a given time, when they are removed and submitted to a mechanical action called slating, which is a method of applying a moving pressure over each skin separately and evenly to press out the foreign matter. This matter was supposed to be lime, but newer evidence demonstrates the following as the more correct view.

Dung contains pepsin and pancreatin, which are formed in the system of the animal; and as there is generally an over-production, the excess passes away with the excrement.

Pepsin transforms albumen to peptones, which are partially soluble and insoluble in water. This, then, is a digesting process, which may be prolonged or shortened, intensified or weakened, at the will of the manufacturer.

The milky liquid forced out of the skin in slating, and which was and still is supposed by some to be lime, contains peptones, insoluble in water.

Immediately following the bating is the drenching or fermentation process. A bath is prepared at about 90° F., composed of water and bran, to which is added occasionally a little wheat or rye flour: this is, however, quite optional, and depends in a great measure on the seasons of the year. After the skins have been placed in this bath, fermentation takes place, accompanied by the formation of the usual vegetable acids, principally acetic acid. The effect of this is to open the skin fibres and swell them, rendering them less compact and dense, and thereby permitting the tannin solutions to act more rapidly and effectively. Should there be any lime present in the skin, by this process it becomes neutralised.

Tanning.—With tanning, practically dyeing commences, because by using separately or combined the various materials for converting skin into leather, shades of colour may be produced from a yellow tint of white to a deep brown.

The lightest shade obtainable is produced by the use of sumac. It is also necessary that the sumac should not contain any trace of metallic salts, especially iron, as these, and particularly the latter, are apt to leave stains which are often troublesome to remove. A yellow tint is imparted to leather when using fine-ground sumac. Sumac gives a soft mellow tannage, not cementing the fibres of the skin together, but leaving them rather isolated. It is a very quick tanning agent, skins being converted into leather by its use in the course of 12 hours. It is absolutely a necessity, where colour is required as white as possible, that the sumac bath should not be allowed to remain too long idle, as the result would be leather of a dark brown shade, consequent on the presence of gallic acid, arising from the conversion of the tannic acid into gallic acid and glucose through fermentation.

Leather tanned with sumac possesses but little capacity for resisting water, but is especially adapted for colouring purposes.

Skins tanned with oak bark are solid and rather hard, and thus more difficult to dye.

Where solidity and wear are required, such being the case where leather is used for binding large heavy ledgers, then oak-tanned leather must be used. One great difficulty confronting the dyer when bark-tanned leather is to be dyed, is the "bloom" on the grain. This is caused during tanning by the infusion of the bark, after exposure to the air, depositing a drab-coloured powder known as ellagic acid upon the skin. Its removal requires the utmost care and attention to safeguard the grain. The use of moderately hard brushes, with warm water in which has been dissolved a small quantity of an alkaline salt, will accomplish all that is needed.

With regard to the application of colour to leather. This material cannot be placed in a dye-bath applied to leather at a heat higher than 110° F., without endangering the existence of the grain in a sound state.

If the skin is left with the grain exposed to the rays of the sun, a dry wind, or frost, before it is tanned, the exposed portions are blasted—that is, the grain is dried and shrivelled up, and a succeeding process probably removes the damaged part, thus exposing the fibre.

Leather to be dyed is usually well washed in a machine adapted for that purpose, and afterwards "cleared" in a solution of acid, preferably sulphuric acid, and water.

The sulphuric acid bath removes to a considerable extent stains from the skin, and precipitates the excess of tannic acid contained in the fibrous portion. It renders the grain more sensitive to the action of most colouring matters by imparting to it a degree of roughness which it did not previously possess. For the vegetable colouring products the skins are washed in several different baths of clean water until no trace of acid is discernible. For very delicate shades requiring the whitest leather, a difficulty often arises from the fact that a satisfactory method of bleaching leather has not yet been discovered.

The process of so-called bleaching in general use consists in depositing lead sulphate on the grain and in the fibre of

the skins. For this purpose a bath is prepared, containing a strong solution of lead acetate, into which the wetted leather is placed and continuously moved for a few minutes. It is then lifted out and put into a bath of sulphuric acid and water. The leather assumes a yellowish colour and harsh touch the moment it comes in contact with the lead acetate, but as quickly becomes almost white, very soft and silky, after immersion in the acid bath. Leather treated by this so-called bleaching process, is, when dry, mellow but firm, and for this latter reason skins are submitted to this treatment to produce a certain finish otherwise not attained.

Leather bleached by this process more rapidly changes to a brown colour when exposed to the atmosphere and sunlight than it otherwise will if left unbleached.

The author has on many occasions attempted to bleach leather by means of hydrogen peroxide in conjunction with ammonia, and although he has not yet succeeded, he thinks it probable that the hydrogen peroxide may be used with fair results if used without ammonia. Ammonia combines with the tannic acid, forming a dark-coloured precipitate, which gives rise to the brown colour appearing on leather which has come in contact with alkali. It causes also the grain to be contracted and very hard and brittle; so much is this the case that leather so treated may, when dried in the open air, be easily broken.

Generally all alkalis have this defect, which is detrimental to their use in leather tanned with vegetable agents.

The use of permanganates proved unsatisfactory.

It is the author's opinion that nature assists the leather manufacturer in a manner in which science has not yet been able to do. As an instance, we find that a cold frosty air produces a decidedly white colour in sun-bleached leather, and for that reason only, skins have often been dipped in hot water and hung up on cords in such a way that the frost may have full power over them to freeze them. It is found that cold alone practically bleaches sun-bleached leather; and not only is it bleached thus, but rendered very soft. When the water contained in the fibres of the skin becomes ice, the fibres are stretched by reason of the expansion of the water freezing, and so the fabric is softened. Afterwards, as the skin dries slowly, the fibres are not contracted rapidly; while, if the skin is dried quickly, the fibres become contracted and brittle.

Dyeing.—The objects desired are to apply colour to the grain in such a manner that it will not easily rub off by various finishing processes into which friction enters largely; that the colour when applied shall be solid and fairly fast to light.

To attain these points many have been the plans adopted to accomplish good results. In dyeing with cochineal it was customary to take the skins just before tanning, therefore in a most critical condition, and after what was called raising them with sodium chloride, to sew them together in pairs so arranged that the grain was outside and the fibrous portion inside. After dyeing the skins were tanned. The expense was heavy and the result sometimes disastrous, the skins becoming damaged in the operation.

Of course the fibre side of the skin was not dyed, and retained its tanned colour. The next step was to dye skins tanned, but in such a way as to give the idea of dyeing before tanning. The reason for this was that the skin is in a very perishable condition before tanning, and cannot be held over indefinitely awaiting orders. This was accomplished by sewing the skins together as before tanning, but still many thought the colour not so good as when dried by the old method. Gradually these ideas changed, until the sewing was dispensed with altogether, and the fibre side, which always takes up the colour very much more rapidly than the grain side, got partially dyed.

The mordants used were also detrimental to a great extent to the leather, and this might be, and doubtless was, lost sight of by the employment of dyers who had previously been engaged in dyeing fabrics. The great aim was to produce fast colours, and in many cases success attended the efforts, but in others the leather was rendered almost useless by using strong alkaline salts. Certainly the size of the skin in almost all instances was reduced through a shrinkage of the fibres caused by mordants. Two agencies appear to work almost exactly opposed to each other, one

being that leather exposed to light gradually becomes darker, the change taking place more rapidly as the light is stronger. Of course it would never become black, but assumes a dark brown shade, especially in sunlight. The other agency is that the dyed colour may with the same treatment become much lighter. The consequence of this dual action is generally that the shade is changed, but to an ordinary observer is not what would be termed faded.

Vegetable Colours.—They do not act too quickly, which may be sometimes an advantage, but their scope is limited. When dyeing with woods, only the clear liquor may be used, otherwise small pieces of wood adhere to the skin and cause dark spots which must be avoided.

Indigo.—Its colour is good, and will not easily be superseded by other colours for some purposes. In dyeing it is used cold, the skins being suspended in the vat for varying periods with repeated exposures to the air to oxidise the indigo. The colour naturally is fixed slowly, but is a good one.

Coal-tar Colours.—The basic colours are not as a rule colours to be depended upon.

Chrysoidine is perhaps the worst in this respect, but still the others are liable to the same faults in a less degree. Another difficulty to be met with is the fact that, excepting chrysoidine, the others have a tendency to bronze.

The colours most useful to the leather-dyer are those which may be worked with a small percentage of acid. About 100° F. is a safe temperature for all leather generally, although with sheepskin a higher temperature may be used—up to, say, 110° F. With calfskin a lower one is preferable. This arises from a different formation of the grain of the respective skins.

The coal-tar colours generally have a strong affinity for the fibre portion of the skin—much more than for the grain—and this presents one difficulty in making use of some shades. Even where precautions are taken to mordant only the grain, the fibre will take up the colour—in fact absorb all the colour in the bath—if exposed to its action.

Great trouble arises when colours are used which are with difficulty soluble in water, or only partially soluble. The small undissolved particles attach themselves to the skin and produce spots which are afterwards difficult to remove.

Where the grain has been blasted or damaged, these particles are to be found firmly rooted, and impossible to remove, while the grain may be somewhat improved by careful washing. It is therefore absolutely necessary that dyes should be perfectly soluble.

There is a point to be arrived at in the use of dyes when the leather will take up no more of one certain colour, but where a different shade will be taken up or combined with the one already used. Advantage is taken of this to cover some defects in the skin, one colour being used which will not show those defects, and when the leather is saturated, then the other colour is used to produce the desired shade. In this way defects may be covered to a considerable extent; but this is one of the most delicate operations of the dyer's art, and one requiring much skill and a great amount of knowledge to accomplish.

If skins are taken when ready prepared for tanning and placed in a dye-bath composed of aniline colours, they rapidly absorb the colour, which will penetrate through the skin. But two reasons present themselves which are obviously sufficient why skins should not be dyed before tanning. The skins are in a critical state of existence, and if submitted to a temperature too hot will dissolve into a jelly known as gelatin or glue; but the principal cause is that the shade may not be sufficiently regulated to match patterns, as the tanning would very materially change the colour lighter or darker.

Staining.—This is another method of applying colour, and one where the coal-tar colours are best adapted of any. In this case, the skin, dry or damp, is laid on a table, all creases or unevenness in the surface of the skin having been previously removed.

The mordant is then applied with a brush, and afterwards the colour, gradually increasing the strength of the latter at each application until the required shade is obtained. Under such treatment the colours must of necessity be quite

soluble in water, otherwise satisfactory results will not follow. The grain is thus not always properly coloured, as a quantity of the dye may be invariably rubbed off the dried surface of the skin by the use of a damp piece of white cotton or other material.

Chamois leather is produced from the fibrous portion of sheep or lamb skins which have had the grain removed by splitting machinery while in the process of liming. Instead of being tanned, as before described, chamois leather is dressed in cod-liver oil; afterwards the oil is removed by maceration and pressure, either in warm water only or by the use of an alkaline bath.

This leather must always retain its softness and flexibility; when coloured, the usual method being to mix colour and clay to a moderately thick consistency, which is then applied with a brush. When dry, the leather is beaten to remove the clay, of course removing also a large amount of colour. But the leather always was dusty and disagreeable.

For several years the author tried to dye this leather without producing harshness, and at the same time at a less cost than was considered necessary, and he accomplishes that end in both directions. The method for dyeing chamois leather madder red is now given, and afterwards the method the author adopts, but without the minute details.

Madder Red.—Dissolve for every 10 or 12 skins, 2 lb. 3 oz. white sugar and 13 lb. of alum free from iron in the required quantity of water, and add $\frac{1}{4}$ pints of spirit of wine, and tread the skins in the solution for two hours.

Before submitting the skins to the process, they should be thoroughly filled with lukewarm water and washed with boiling water, and after passing through dilute sulphuric acid (1 part in 60 of water) subjected to a final washing. After working the skins thoroughly in the solution, remove from the vat, wring slightly, rinse in water, and dry in the shade. After partial drying replace them in the same bath, to which in the meanwhile has been added warm water and about one quart of spirit of wine; allow them to remain one hour with occasional working. After the skins, by repeated wringing out and replacing in the bath, have been thoroughly soaked through, and passing them once more through the bath, spread them in piles upon a table for two or three hours.

The skins thus prepared are now mordanted for madder red. This is prepared by mixing 20 pints of the foregoing mordant with one pint of tin composition and 20 gallons of water. After stirring the mixture thoroughly, full or tread the skins in it for one hour.

Remove and allow to drain, and draw them from time to time through the mordant. Then hang the skins in the shade to dry, afterwards in a room heated to 86° F., where they should remain at least 12 hours. When dry, rinse in cold water, then full in cold water and rinse once more.

Prepare the madder bath by adding 8 $\frac{1}{2}$ lb. good madder to 37 to 42 gallons of water in a boiler heating gradually to a temperature not exceeding 122° F.

Place the skins in the bath one by one, and after allowing them to remain till the above temperature is reached, five or six hours being generally required, place them at once in running water, and after thoroughly rinsing and repeated fulling upon the stone, hang them up to dry. To give the leather lustre, it is placed in the fining bath, prepared by mixing 26 $\frac{1}{2}$ gallons of water, half-pint spirit of wine, and one-third pint olive oil. Tread the skins thoroughly in this bath, rinse once more and dry.

To restore softness to the skins dyed, tread them in a mixture of 100 yolks of eggs, 1 lb. 2 oz. alum, and the necessary quantity of water, dry and work with a stretcher.

The method the author adopts to produce, not red only, but the majority of colours, is as follows:—

The skins are washed in warm water—say one dozen skins are washed in five minutes. They are then placed in a warm bath about 90° F., containing the mordant, where they remain with an occasional agitation for 10 hours. They are then taken out, allowed to drain awhile, and then placed in the dye-bath at 105° F. In 30 minutes they are dyed, washed through warm water and dried. If for a light colour, the skins are previously hung in the open air after mordanting, which bleaches them slightly. If a very light

colour, the skins are bleached in the open air before mordanting.

The skins require no further treatment beyond the usual stretching in finishing.

The Colouring of Paper with Coal-Tar Dyes. Papier Zeitung, 1891, 16, 2182—2183.

Of substantive dyestuffs the following are suitable for use in colouring paper: Congo, Congo RG, Congo 4 R, Brilliant Congo, Benzopurpurin, Rosazurin, Deltapurpurin, Hessian purple NB, Azo-orseillin, Chrysamine, Congo yellow, Brilliant yellow, Chrysophenine, Hessian yellow, Azo blue, Azo violet, Heliotrope, Rosazurin 2 B, Congo Corinth, Benzo brown, Violet black, and Benzo-black-blue. To apply them, the paper pulp is heated with a solution of 0.5 to 3 per cent. (calculated on the weight of dry paper) of the dyestuff, corresponding to the shade desired, and a small proportion of sodium carbonate, phosphate, or chloride, or a larger proportion of sodium sulphate. Thus, paper is dyed with Hessian purple by well mixing it in the state of pulp with a solution of from 0.5 to 2.5 per cent. of the dye, 1 per cent. of sodium carbonate, and 10 to 20 per cent. of sodium sulphate, and then heating the mixture for half an hour.

In the class of basic dyes the following are commendable: Magenta, Cerise, Grenadine, Safranine, Rhodamine, Pyronine G, Acridine orange, Auramine, Phosphine, Malachite green, Brilliant green, Azine green, Victoria blue, New blue, Methylene blue, Muscarine, Neutral blue, Basic blue, Soluble blue, Capri blue, Methyl violet, Crystal violet, Hofmann's violet, Vesuvine. These are fixed on a mordant of tannate of antimony:—A solution of the necessary quantity of dye (0.5 to 2 per cent.) to produce the desired shade, is first thoroughly incorporated with the pulp (which is heated to a temperature of 50°—80°), then a solution of tannic acid is added and mixed, and finally a sufficiency of an antimony salt to precipitate the tannic acid.

Eosin, Erythrosin, Phloxin, Rose Bengale, Alizarin, and Victoria blue B, are employed in conjunction with an alumina (aluminium acetate, basic alum, aluminium basic sulphate, or aluminium sulphite) or tin oxide (from stannous chloride) mordant.—E. B.

The Permanence of Colours used in Printing towards Light.

G. Fritz. Papier Zeitung, 1891, 16, 2213—2214.

CARMINE when used in thin consistence is somewhat sensitive towards light, but in thick consistence it is very permanent. Tints such as "rose" from Carmine, and white lead become reddish-grey after a long period, this being due to the action of the air on the white lead; and, although Carmine is itself very permanent, the tints obtained with it in admixture with other substances, invariably become darker after a time. The most permanent violet is that from Carmine and Ultramarine, but it ultimately becomes bluish. Natural madder-lake exhibits the same behaviour as Carmine, whilst the artificial from anthracene is much more fugitive. Cinnabar with the addition of a suitable varnish is very permanent, but with a varnish containing lead it soon becomes black on exposure to the air. The so-called "Carmine-cinnabar" becomes lighter or darker according to the material of which it is made. Minium changes to a brownish colour in the air, but becomes black in the presence of sulphuretted hydrogen. Ultramarine is by itself very permanent, but when mixed with lead compounds undergoes change; in order to obtain a blue tint from Ultramarine, it is best to mix it with zinc white. Prussian blue and other similarly constituted compounds when used in thick consistence retain their colour for a long time, but in thin consistence soon become greenish, the latter change being hastened when rosin varnish or rancid oils are used conjointly. Cobalt blue is very permanent both towards light and air, and Carmine yellow is but slightly altered; lead dryers cannot however be used with the latter. Chrome yellow becomes darker with age, and finally loses its original colour entirely. White lead becomes yellow on exposure to the air; and greys formed by mixing it with blacks become brownish; it quickly turns brown when mixed with rosin varnish. Zinc white is much more permanent than white lead, and it can be used in admixture with any of the numerous sulphuretted colouring

matters. Despite its advantages however, it is not largely used in printing; it does not possess so great a covering power as white lead. Baryta-white is extremely permanent, but its covering power is only very small. Paper containing free acid or chlorine should not be employed for colour printing.

The author considers that the nature of colouring matters used in printing may be determined by treating a small quantity with alcohol, which dissolves all the coal-tar colours that are employed, and observing the colour of the solution, or by igniting a portion in the blow-pipe flame. In the latter case cinnabar volatilises completely, zinc-white shows the well-known change of colour, and lead compounds usually leave granular residues of metallic lead; the presence of these metals can then be confirmed by dissolving the residues and applying the known tests.

The editor points out in a note that alcohol is not an infallible test for coal-tar colours, inasmuch as a not unconsiderable number of the colouring matters obtained from dye-woods are also soluble in it; whilst very many coal-tar colours dissolve in alcohol with tints other than their own. He appends a table showing the colour of the solutions which result when certain colouring matters are treated with nitric acid, hydrochloric acid, sulphuric acid, ammonium sulphide solution, and solutions of caustic alkalis.

—A. R. L.

PATENTS.

Improvements in the Extraction of the Extraneous Matters from and in Bleaching Vegetable Fibres. J. Smith and P. W. Nicolle, Jersey. Eng. Pat. 17,083, December 31, 1884. Amended November 19, 1890. 6d.

THE use of alum and other double sulphates for ungumming China grass (rhea), Manilla, or other textile fibres, is disclaimed, the claims being confined to the employment of alkaline sulphates for that purpose (see this Journal, 1885. 743).—E. B.

Improvements in Mechanism or Apparatus for Dyeing and Bleaching Cotton, Wool, Silk, and other Fibrous Materials in the Raw and Manufactured or partly Manufactured State. G. Young, Winton; F. Pearn, Gorton; and W. Crippin, Patricroft. Eng. Pat. 1157, January 22, 1890. (Second Edition.) 1s. 1d.

THE mechanism forming the subject of this invention is employed for bleaching and dyeing textile fibres in the unmanufactured, manufactured, or more especially, partly manufactured state. The figure below shows a sectional elevation of one modification of the apparatus, which is used in bleaching, &c. yarn in the form of cops.

APPARATUS FOR DYEING AND BLEACHING.

It consists of a vat *a*, supporting a larger chamber *b*, smaller chamber *f*, and treating chamber *h*. The chambers *h* and *b* are connected by the pipe *c*, and the chambers *h* and *f* by the pipe *f*². A slide valve (not shown in Fig.), opened or closed by the movement of a rod *e*¹, puts the chambers *b* and *f* alternately into communication with an exhausting apparatus. The movements of this rod are controlled by a lever *g* (pivoted on a bracket *g*¹ fixed outside the chamber *b*) which is connected by a rod *g*² with a beam lever *l*. The latter, which is automatically depressed by a slotted rod *m*¹, when the float *m* on the surface of the liquor *x* falls, is provided with two pins *l*² which, with the rise or fall of the lever, move the handle *k*² of the three-way tap *h* through an arc of 60°, and thus admit either steam or air through a passage in the wall of the chamber *h* into an annular recess *h*¹, whence it issues into the chamber through a perforated ring *h*². The other passage in the tap serves for the admission of gas into the chamber *b*, when required. A pawl *n* catches in a notch *l*¹ in the lever *l*, when the lever and the slide of the slide valve are in their middle position (in which case the tap *h* and the ports in the slide valve are closed), and arrests the automatic action of the machine. The cops to be dyed are wound on perforated hollow spindles which are placed in holes in a circular plate *j*, which rests on an india-rubber ring *j*¹, and is provided with a handle *j*² for facilitating its removal with the cops from the chamber *h*. (During the operation of the machine this chamber is closed by a hinged lid *h*³.) Underneath the plate *j* are two mushroom valves: one of these, *e*², opens when the receiving chamber *b* is being exhausted, and allows the liquor to pass towards this chamber, but closes against its return; the other, *f*², similarly allows steam, air, or gas to pass from the chamber *h* to the receiving chamber *f*, but not vice versa. The end *e*³ of the pipe *c* communicates by a lateral passage with the space *e*⁴ above the valve *e*², and thence with the passage *e*⁵ which is common to both valves. This passage *e*⁵ communicates directly with the cavity *d* under the stationary plate *j*, on which the cop spindles are placed.

The cops are dyed by pumping the air out of the chamber *b*, which causes the dye-liquor to be drawn up the wide conical pipe *h*⁴ into the space surrounding the cops, whence it passes through the cops into the pipe *c*, and thence into the chamber *b*. After the liquor has been drawn for some time through the cops in this fashion, the slide of the slide valve is automatically moved, and air admitted into chamber *b*, whilst chamber *f* is exhausted, and steam or air is drawn through the cops, the liquor in *b* passing back into the vat through a valve arrangement at *e*¹. This alternate treatment with dye-liquor and steam or air is repeated until the cops are sufficiently dyed.—E. B.

Machine for Printing Floor-Cloth and similar Material by means of Flat Blocks. T. Dale, Kirkealdy. Eng. Pat. 1210, January 23, 1890. 8d.

THE chief feature of this invention is the employment, in connexion with the printing blocks, of one or more cylinders with pistons operated by compressed air or steam, but preferably by the former, so dispensing with the usual gearing shafts or cams. A second feature is the employment of such cylinders in connexion with mechanism for giving a longitudinal motion to the linoleum which is being printed. Details of the mechanical arrangements cannot be properly given apart from the drawings which illustrate the specification.—E. B.

Improvements in the Method of and Apparatus for Mordanting and Dyeing Wool, Cotton, and other Fibre, and also for Extracting or Separating Animal from Vegetable Fibre. John Smith, I. Smith, and Joseph Smith, Halifax. Eng. Pat. 1607, January 30, 1890. 8d.

THE wool, &c., to be dyed or otherwise treated is introduced into a long shallow vat, which is supplied with a continuous stream of liquor, in the form of a spray, from a tank fixed above it at the end where the wool enters, the liquor flowing away over a bridge at the opposite end of the vat. The

wool is carried along in the stream of liquor, but is, at intervals in its course, caught and dipped below the surface of the liquor by perforated "dipping-rollers or other mechanical equivalents;" or it may be carried through the vat on an endless perforated sheet; or, again, it may be placed on a stationary perforated tray underneath the tank. Further, the employment is claimed in combination with the above mechanism of a pump for raising the liquor from a low-level tank, into which it flows from the vat, into the tank above the vat. Two sheets of drawings accompany the specification.—E. B.

Improvements in Compositions for Renovating the Faded Colours of Plush, Velvet, Cloth, or other similar Material. W. P. Thompson, London. From A. Mautner, Vienna, Austria. Eng. Pat. 1717, February 1, 1890. 6d.

THE colour of faded plush, &c., is completely restored by the application of one of the under-mentioned mixtures, which is spread over the faded parts by means of a brush or "mop," allowed to dry, and then well brushed, the material thus being renovated without being removed from furniture, &c. A "basis" is prepared of yolk of egg (0.4 part), caseine (4), ammonium hydrate (8), tartaric acid (2), gelatine (1), Venetian soap (1.5), alum (2), distilled water (80), egg albumen (1), and sodium nitrate (0.1). In this mixture appropriate dyes are dissolved; thus, there are added:—

For the renovation of red materials, 0.1 to 1.0 part of "pure red."

For the renovation of blue materials, 0.1 to 1.0 part of Lyons blue and 0.1 to 0.5 part of "nigrysin."

For the renovation of brown materials, 0.1 to 0.1 part of pure genuine brown and 0.1 to 0.5 part of "nigrysin."

For the renovation of green materials, 0.1 to 0.5 part of Lyons blue, 0.1 to 1.0 part of "nigrysin," and 0.1 to 0.4 part of "Martin's yellow."

For the renovation of yellow materials, 0.1 to 1.0 part of "Martin's yellow."—E. B.

Improvements in Dyeing Cotton. T. Ingham, Manchester. Eng. Pat. 2411, February 14, 1890. 4d.

A BLACK is produced on cotton materials by passing the same through an oxidising bath of sodium dichromate, after impregnating them with a solution of logwood extract at 3° Tw. (1 gallon) to which there are added Alkali blue (2 oz.) and crystallised sodium carbonate (4 oz.) Instead of, or along with, the Alkali blue in this bath, Alkali yellow, bark liquor, or fustic liquor, may be used. The composition of the (logwood) colouring bath is alone claimed.—E. B.

Improved Method or Process of and Apparatus for Bleaching, Dyeing, or otherwise Treating Fibrous Materials. S. D. Keene, Providence, U.S.A. Eng. Pat. 3009, February 25, 1890. 8d.

THIS invention relates to the bleaching and dyeing of cotton or other vegetable textile fibre, more especially when in the form of yarn or cops, spools or bobbins, or in a loose state. The material is enclosed in a keir from which the air is exhausted; then the air-exhaust passage leading from the keir is closed, and the bleaching, &c., liquors admitted into the keir and forced into and through the yarn by a force-pump or by means of compressed air. The apparatus in and by which these operations are successively performed is described in the specification by the aid of a drawing.

—E. B.

Improvements in Expediting and Improving the Process of Bleaching Linen, Cotton, and other Textile Fabrics, and Linen, Cotton, and other Yarns in the Hank. R. T. Webb, Newtownards. Eng. Pat. 6612, April 30, 1890. 8d.

IN this process a pair of squeezing rollers is arranged above the vat containing the boiling lye or other chemical solution used in the process of bleaching the material, and the

latter is passed between the rollers and through the liquid a sufficient number of times to ensure the proper action on it by the liquid.—H. S.

Improvements in the Method of and in Means and Appliances for Tarring, Colouring, and otherwise Preparing Thread, Hemp, Jute, or other Twine for Sewing, and in Feeding or Supplying the same to Sewing Machines. W. Peters, London. Eng. Pat. 7423, May 13, 1890. 8d.

This invention has for its subject an apparatus which enables the use of thread in sewing machines direct from the tarring, colouring, or preparing tank, this tank being water-jacketed and heated. The thread is passed through suitable rollers as it is withdrawn from the liquid, and these rollers are geared to run at a speed corresponding to that of the sewing machine. The motion is derived by means of a band off the motion-shaft of the sewing machine.—H. S.

Process for obtaining Designs or Patterns in Red Colour, on Textile Fabrics Dyed with Indigo. W. Elfers, Hagen, Germany. Eng. Pat. 7522, May 14, 1890. 8d.

The indigo-dyed cloth is prepared with sodium β -naphtholate, dried, printed with a colour-mixture of sodium chromate, sodium nitrate, stannous chloride, acetate of alumina, acetate of lime, and diazoazobenzene chloride, again dried, aged for 12 hours, passed through a bath of oxalic acid and dilute sulphuric acid at 44° C., and finally well washed and dried. Sodium nitrate and stannous chloride are added to the printing-mixture for the purpose of increasing the intensity and brilliancy of the red, and acetate of alumina and acetate of lime to protect the same against the action of soap.—E. B.

Improvements in and in the Preparation of "Wash Greys" or Back Cloth used in Printing Woven Fabrics. G. B. Behrens and J. C. Watson, Castleton. Eng. Pat. 7417, June 18, 1890. 1d.

Grey cotton cloth is treated with caustic soda and then with a preparation of albumen and zinc sulphate solution in order to fill up the interstices of the cloth and at the same time render it more durable and waterproof. The material so produced is said to be cheaper and an improvement on the ordinary "wash grey" at present in use in the process of printing woven fabrics.—H. S.

Improvements in Apparatus for Boiling, Scouring, or Cleansing Textile Fabrics. W. Hutchinson, Salford. Eng. Pat. 10,323, July 3, 1890. 8d.

This apparatus consists of a vat or tank containing the scouring liquid, kept boiling by perforated steam pipes, and is fitted with five sets of rollers or pulleys; the two upper sets may either consist of rollers or a number of pulleys, and between them is passed the cloth, the liquid being pressed therefrom by flat weights resting on the journals of the uppermost pulleys. The other sets are arranged under the first set, and near the bottom of the tank. They serve to guide the cloth through the scouring liquid, repeating this operation before the material is again passed under the rollers. The object of this invention is to enable the repeated removal from the liquor of textile fabrics which are treated with a boiling alkali or other liquor in the process of bleaching, and to remove the scouring liquid with which the cloth is saturated before it re-enters the main body of the liquor.—H. S.

Improvements in Dyeing Cotton. T. Ingham, Manchester. Eng. Pat. 14,302, September 11, 1890. 4d.

Cotton cloth or yarn is dyed black by the following process:—

The material, after being scoured, is passed through a bath composed of logwood liquor at 3° Fw. (1 gall.), copper sulphate (4 oz.), and acetic acid at 8° Tw. (1 pint).

It is then dried and the black produced by passing it through a solution of sodium or potassium dichromate. To modify the shade of black, a certain proportion of a yellow colouring matter (fustic, bark, Persian berries, or galloflavin) may be added to the logwood bath.—E. B.

Improvements in Oil-cloth and other Fabric Printing Presses. W. H. Townsend, New York, U.S.A. Eng. Pat. 14,699, September 17, 1890. 1s. 1d.

This invention, which cannot be intelligibly described apart from the drawings given with the specification, relates to improvements in mechanism for printing oil-cloth, more especially in the mechanism patented in the United States of America by C. Rommel (U.S. Pat. 137,962 of 1873.)

—E. B.

Improvements in the Method of and Apparatus for Scouring and Dyeing Yarns, Tops, and the like. W. Laidlaw, Hawick. Eng. Pat. 16,751, October 21, 1890. 8d.

The yarn, &c. is loosely packed in perforated cages F (see figure) attached to endless pitch-chains E, which pass over pulleys D.

APPARATUS FOR SCOURING AND DYEING.

The framework C, on which the pulleys are mounted, is so constructed that it may be raised from, or lowered into, the vat A, whilst the chains are in motion.

One advantage attending the use of this apparatus is, that the yarn, after being scoured, may be dyed without being removed from the cages, this being accomplished by simply emptying the vat of the scouring liquor and filling it with dye-liquor.—E. B.

Improvements in Machines for Imparting to Paper and other Sheet Material a Variegated or Marble-like Appearance. C. H. Bellamy, South Hadley Falls, U.S.A. Eng. Pat. 16,795, October 21, 1890. 1s. 3d.

The object of this invention is to provide suitable mechanism for performing the "marbling" of paper, which has hitherto been chiefly done by hand. It comprises a tank for holding a solution of gum or other "colour-supporting

liquid;" an apparatus for distributing the colour on the surface of the gum solution; and mechanism for conveying the paper to, and removing it from, the colour. Eleven sheets of drawings, aiding the description of the mechanical arrangements, accompany the original specification. There are 31 claims.—E. B.

Improvements in or Relating to Photo-Mechanical Colour Printing. F. J. Upton, London, and G. Stephens, Walthamstow. Eng. Pat. 1793, January 31, 1891. 8d.

See under XXII., page 947.

A Process of Imparting a Permanent Colouring to Turquoises and other Precious Stones. A. J. Boulton, London. From A. Kühne, Dresden, Germany. Eng. Pat. 14,385, August 25, 1891. 4d.

TURQUOISES and other similar precious stones are frequently defective in colour, exhibiting in some parts spots of a different hue to other parts; moreover, in course of time their colour fades. To remedy these defects the stones are coloured by means of "aniline colours." The stones are first immersed in a dilute solution of tartaric acid (20 grms. per litre) or in a solution of tartaric acid (10 grms. per litre), and copper or iron sulphate (40 grms.). They are then placed in a bath of alcohol, to which the dye, dissolved in a little water, is gradually added. In this bath the stones are left for 24 hours, after which the colouring matter will be found "to have permeated them not only on the surface, but a certain distance inwardly, so that they may be cut or ground without losing any of the uniformity of their colouring."—E. B.

The author has made thermo-chemical determinations, which have enabled him to demonstrate with greater precision than has hitherto been done, the correctness of the last-mentioned theory. Chromium sulphate was the salt chosen for the investigation, since it is more stable in the green-coloured state than the chloride or nitrate. Various measured volumes of a solution of sodium hydrate were added to solutions of this salt, containing on an average one equivalent of the salt per six litres of water, and the heat evolved measured. Then the equivalent to the soda employed of dilute sulphuric acid was added to the solution, and the thermal disturbance again measured. In this way it was found that the green solution contained exactly half an equivalent of free H_2SO_4 per equivalent of $Cr_2O_3 \cdot 3 SO_4$. It thus appears that the basic green salt formed by the action of heat on a normal solution of chromium sulphate has the definite composition of $2 Cr_2O_3 \cdot 5 SO_4$, and that it contains a modified form of chromic oxide which is incapable of combining with more acid than the formula indicates. This modified oxide, moreover, the author submits, is not capable of existence in the free state, for when the base is precipitated by an alkali, it combines with only two molecules of H_2SO_4 , as the following experimental results show:—

Reaction.	Heat-Units Evolved or Absorbed.
Cr_2O_3 (precipitated from the green solution) + 2 H_2SO_4 (in solution) = $Cr_2O_3 \cdot 2 SO_4$ (in solution)	+ 17.4
$Cr_2O_3 \cdot 2 SO_4$ (in solution) + H_2SO_4	= 0.4

The presence of sodium sulphate in the solution accounts for the slight absorption of heat in the latter experiment, the acid reacting with this compound.—E. B.

Experiments on the Alterations undergone by Chloride of Lime. A. Boyer and L. Durand. Ann. Soc. Ind. de Lyons, September 1891.

Dry chloride of lime alters about twice as quickly in the open air as in a room; in the open air, also, the decomposition is quickest in a dry atmosphere with a high wind. In rooms, the alteration is slightly quicker in light than in darkness, about one-eighth being the exact amount. In an atmosphere containing H_2S , CO_2 , and HCl , the alteration is about $3\frac{1}{2}$ times as rapid as in ordinary atmosphere. A solution of chloride of lime alters about six times as rapidly in the open air as in a closed room. The method of titration by means of methylene blue has given very exact results. Solutions exposed in a dark room or in a yellow flask gave titrations identical with either sulphate of indigo or methylene blue; but with solutions exposed to light, the titrations given by sulphate of indigo are totally inaccrurate, and entirely inadmissible. Solutions of chloride of lime alter twice as quickly in light as in darkness. A solution placed in an open vessel alters about $1\frac{1}{2}$ times as quickly as one in a closed vessel. A solution placed in a room and receiving light through a curtain was altered just as quickly as one receiving the full light of the sun, but no oxides of chlorine were formed.

Preparation of Ammonium Sulphide. E. Donath. Chem. Zeit. 1891, 15, 1021.

See under XXIII., page 949.

PATENTS.

Improvements in the Manufacture of Hydrate of Alumina from Silicates of Alumina or Clay. E. Meyer, Berlin, Germany. Eng. Pat. 14,084, September 8, 1890. 6d.

THE patentee finds that aluminium silicate, or mixtures thereof with other silicates or oxides, is decomposed by means of superheated steam into silicic acid and aluminium

VII.—ACIDS, ALKALIS, AND SALTS.

Action of Heat on Solutions of Salts of Chromic Oxide. A. Reouma. Compt. Rend. 1891, 112, 1439—1442.

SOLUTIONS of normal salts of chromic oxide, as is well known, become green on boiling, and on standing for some time at the ordinary temperature, re-assume their purple colour. The cause of these changes has been variously explained. Berzelius, Loewel, and Fremy have stated it as their opinion that chromic oxide in the form of a dissolved salt, is modified by heat, but have given no explicit reason for this belief, except that the base precipitated from green chromium salts possesses different properties from that precipitated from purple salts. Schrötter considers the change of colour from purple to green to be due to a partial dehydration of the chromic salt in solution. This hypothesis, however, has been refuted by Loewel. The theory which at the present time is held by the majority of chemists is that a normal chromic salt in solution is decomposed by heat into a soluble, green-coloured, basic salt and free acid or an acid salt. Krüger and Siewert support this theory on the ground that certain bodies, such as alcohol, precipitate green basic salts from chromium solutions of the same colour, but overlook the fact that the formation of these salts may be due to an interaction of the precipitant employed. The strongest evidence in favour of this view is, however, afforded by the discovery, made by Van Cleef, that the green solution of a chromium salt is separable by dialysis into two portions, one of which (passing through the dialyser) contains more acid, and the other less acid, than a corresponding solution of the normal salt. That such a decomposition of the normal chromium salt takes place, was indeed to be expected, seeing that Berzelius has shown that the analogously constituted ferric salts undergo a similar change.

hydrate, whilst the oxides are transformed into hydrates. The finely-ground silicate may be suspended in hot water, through which superheated steam is caused to pass; the reaction is promoted by the addition of, say, 5 cc. hydrochloric acid per 10 grms. of clay. The silica is filtered off, and from the sufficiently enriched solution the alumina is precipitated by means of ammonia, preferably after the addition of sulphuretted hydrogen, for retaining the iron in solution. In an alternate way of working, the silicate is formed into porous bricks which are brought to a high temperature in a suitable vessel, whilst a current of steam is blown in. The resulting mass is treated with water and the solution treated as above.—H. A.

Improvements in the Preparation of Aluminium Fluoride and Double Fluorides, and in the Manufacture of Aluminium from Fluorides. T. S. Lindsay, London. Eng. Pat. 16,887, October 23, 1890. 6d.

THE object of this invention is the preparation of a double fluoride of aluminium and alkali (or alkaline earth), which presents advantages for the production of aluminium, owing to the large proportion of aluminium fluoride contained in the same. Three alternate methods are given for the preparations. Alumina or its hydrate is dissolved in hydrofluoric acid, treated with 2 mols. of an alkali (hydrate or carbonate) or the equivalent of an alkaline earth, and sufficiently boiled for precipitating the new double fluoride; or the alkali may be substituted by an alkaline or alkaline earth chloride; lastly, any of the above mixtures of alumina with an alkali, alkaline earth, or chloride, may be dissolved in hydrofluoric acid and treated as before.

Any of the new double fluorides may be directly treated with sodium in the usual way for the production of aluminium. When ammonium double fluoride is employed it is previously heated in order to drive off its ammonium fluoride which is collected for future use, the pure aluminium fluoride remaining behind being then reduced with metallic sodium.

The proportion of sodium used should be such, that the slag produced should have the composition of a potassium or sodium cryolite. This slag may be treated with sulphuric acid for the production of hydrofluoric acid, and the sulphuric acid can be used in such proportions that the product of the reaction, after washing out the sodium sulphate, should be an aluminium double fluoride, which returns in the process.—H. A.

Improvements in the Employment of Sulphuretted Hydrogen in the Manufacture of Alkali and Certain Bye-Products. J. Simpson, Liverpool. Eng. Pat. 17,765, November 5, 1890. 8d.

THE object of this invention is the utilisation for the manufacture of alkali, of certain forms of neutral or acid sodium sulphate, such as cylinder cake, nitre cake, waste liquors from the wet copper process, or native sulphate. The free acid present in the saturated solution of these substances is first of all neutralised with calcium sulphhydrate, the clear liquor separated from the precipitate consisting of gypsum and iron, and treated with sufficient calcium sulphhydrate for conversion into sodium sulphhydrate and gypsum. The reaction is facilitated by carrying it on in closed vessels, under a pressure of 60–80 lb. per square inch, under which conditions calcium sulphate is insoluble in the liquid. The clear liquor is carbonated in Solvay towers, the nitrogen which is given off at first allowed to escape, and the sulphuretted hydrogen is passed in milk of lime for the regeneration of calcium sulphhydrate (see this Journal, 1891, 611).—H. A.

Improvements in Reverberatory Furnaces. F. Ellershausen, Hebburn-on-Tyne. Eng. Pat. 17,815, November 5, 1890. 6d.

IN the manufacture of alkaline sulphides great difficulties have been experienced owing to the corrosive action of the

sulphides on the bed and lining of the furnace, more so when the temperature rises too high, which is apt to happen especially near the fireplace. To prevent overheating, the bridge of the improved furnace is elevated to about 2 ft. above the bed, and is provided with a horizontal air shaft for the cooling of the same; the neck tapers from the fireplace towards the hearth, by which means the flame is directed on the charge; finally the bed near the bridge is inclined to prevent contact of the alkaline sulphide and the bridge. The walls of the heating chamber are faced with fire bricks, tiles, or slabs, which can be easily removed and replaced.

Three sheets of drawings accompany the specification.

—H. A.

Improvements in Process and Apparatus for Procuring Cyanogen and its Compounds from Gases. H. H. Leigh, London. From J. Elsner, Paris, France, and R. Gasch, Mainz, Germany. Eng. Pat. 8293, May 14, 1891. 6d.

THE waste gases from blast furnaces, or the gases from other processes involving the dry distillation of coal, contain ammonia and cyanogen compounds, the recovery of which has so far not been successful. It is proposed to scrub the gases in question with a solution of sulphate or oxalate of an alkali (or magnesia or alumina), holding iron sulphide (or another metallic sulphide) and lime in suspension. A weak solution of sodium ferrocyanide is thus obtained, whilst the lime is converted into calcium sulphate and sulphide, which in settling, carry down the "brown bodies" and other impurities of the solution. In order to enrich or concentrate the solution, one part of it is acidified and precipitated with a soluble iron salt; the neutral or basic Paris-blue so formed is dissolved in the remaining part of the solution, whereby it is not only enriched, but gives rise to the formation of iron sulphide which can be used over again. The operation is repeated until the solution of sodium ferrocyanide is of the desired concentration.—H. A.

Improvements relating to the Extraction of Carbonic Acid from Minerals, and to Apparatus therefor. A. L. H. Knoop, Minden, Germany. Eng. Pat. 13,334, August 6, 1891. 6d.

THE finely-ground mineral is charged in the annular space formed by two tubes; the fire-gases are passed in the shorter inner tube, from whence they are conducted by means of flues round the outer tube, in such a manner that the layer of mineral is heated from both sides. Under the influence of heat the particles of carbonate lose their power of adhesion, and on a valve or door fixed to the bottom of the apparatus being opened flows out like dry sand, whilst the insufficiently heated particles remain between the tubes.

—H. A.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

PATENTS.

Improvements in the Treatment of Minerals used in the Manufacture of Glass, China, Earthenware, and similar Goods. G. L. Schultz, London. Eng. Pat. 16,629, October 20, 1890. 4d.

THE object of the patentee is to remove iron from the raw materials used in the manufacture of glass, china, and earthenware, by treatment with an acid, preferably hydrochloric acid, followed by washing and the addition of a small quantity of alkali to remove the remaining traces. The process "has special reference to a material called granulite, Meldon stone, found in the neighbourhood of Okehampton, Devon, and elsewhere, but has reference also to the treatment of other stone, such as Cornwall stone, clays, and sand."—B. B.

Improvements in Machinery for making Fireclay Retorts, Slabs, Sanitary Pipes, and other like Articles. T. C. Fawcett, Leeds. Eng. Pat. 16,808, October 22, 1890. 8d.

THE process patented has reference to vertical hydraulic presses for making fireclay goods, water pipes, and the like, in which the upward stroke of the piston of the ram, (which is so arranged that the quantity of water used in the upstroke is small compared with that needed for the down stroke), forces the water that has been used for the down stroke back into an auxiliary overhead tank, which is used to supply water to send the ram the greater part of the way on its downstroke without having recourse to the high pressure supply from the accumulator or pumps. The downstroke of the ram is then completed by water from a high pressure supply in the ordinary way. When used to press bricks or slabs the upper end of the vertical hydraulic cylinder is provided with a second piston actuating a cross-head connected by long vertical bolts to a second cross-head below the hydraulic cylinder, which brings pressure to bear on the moulding die, and thus presses the brick at the bottom at the same time that it is being pressed by the ram proper on the top.—B. B.

Improved Means of Manufacturing Glass Vessels and Adapting the same for the Storage and Conveyance of Compressed Gases, and for similar purposes. D. Rylands, Stairfoot. Eng. Pat. 17,117, October 27, 1890. 8d.

THE object of the patentee is the manufacture of glass vessels for use in bottling compressed carbonic acid gas, oxygen, &c., and for allowing the easy withdrawal of the contents when required, and for providing the vessels with a suitable protecting cover. The method of manufacture consists essentially in pouring the "metal" into a mould and making it into the form of a tube by means of a pressing plunger, the exterior mould and the pressing plunger being afterwards withdrawn and the tube made to assume its final shape by blowing until it fits an exterior mould, the closed end being simultaneously formed by the use of a separate mould bottom brought into place before the blowing is begun.

The tube is formed with a screw thread, internal or external, complete or interrupted, as may be desired, by which it may be attached by a cap carrying a valve or cock. The tube is protected by an outer case of wood or similar material well packed with sawdust and strengthened by iron bands.—B. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Asphaltum and Ozokerite in the United States. E. W. Parker. Eng. and Mining J. 1891, 193—194.

See under III., pages 910—912.

Portland Cement. Dingl. Polyt. J. 281, 114—116, 138—141, 163—167.

Cement Testing.—The rules for testing cement in Austria are practically identical with those employed in Germany. The method of ascertaining whether a cement is free from any tendency to blow or expand in air consists in the employment of the firing test in conjunction with the wet pat test. The first is carried out as follows:—The cement is gauged with water to the normal consistency and spread out upon two glass or metal plates in the form of pats 10 cm. in diameter, and 1 cm. thick. In order to avoid shrinkage cracks, the pats are protected from draughts and direct sunlight, preferably by being kept in a moist chamber. After 24 hours they are gradually heated in an air oven to a temperature of 120° C., for two or three hours, until all perceptible water vapour has been driven off. Should radial cracks appear at the edge of the pat, the cement is unfit for use in air; these cracks must be carefully distinguished from mere shrinkage cracks which do not make their appearance at the edge. The cracking of cement due to the presence of calcium sulphate is not detected by this test, but becomes evident from the result of the wet pat test; when both tests are satisfactory the cement may be considered sound. The suitability of cement for use under water is best gauged by its behaviour under the wet pat test; the same precautions to avoid the formation of shrinkage cracks as are necessary in the firing test should be taken. The pat, after being allowed to set for 24 hours, is kept in water for 27 days. The tests for fineness and strength in tension and compression call for no special remark.

A. Foss has experimented with the apparatus devised by J. Holmblad for determining the percentage of lime in mortar at the actual place of building. The process consists essentially in titrating a measured quantity of mortar with hydrochloric acid, the vessel from which the latter is poured being graduated so that one division equals one per cent. of calcium hydrate calculated on the dry mortar. The assumption is made that mortar contains on an average 14 per cent. of water. Ordinary good mortar contains 8 to 10 per cent. of calcium hydrate.

The following are some of the results given by cements examined for the Association of German Cement Makers by Fresenius:

Specific Gravity.		Loss on Ignition.	Magnesia.	Strength; Kilos. per Sq. Cm.		Residue left on		Behaviour on Setting.
Unignited.	Ignited.			Compression.	Tension.	5,000 Mesh.	300 Sieve.	
3'011	3'166	3'371	Per Cent. 1'46	212'5	18'4	27'0	6'3	Slow-setting.
3'126	3'185	1'606	0'80	212'5	21'3	27'5	8'0	Quick-setting.
3'083	3'118	1'565	1'05	190'0	20'9	27'2	6'0	Slow-setting.
3'130	3'150	1'15	1'705	170'0	17'1	28'7	7'5	Slow-setting.
3'055	3'131	2'05	3'064	160'0	17'4	20'5	1'7	Slow-setting.
3'103	3'219	1'19	1'104	210'0	20'4	18'0	3'5	Quick-setting.
3'076	3'176	2'77	1'69	202'5	20'6	20'5	2'7	Quick-setting.
3'072	3'175	2'45	1'92	220'0	21'8	23'2	3'0	Slow-setting.
3'144	3'234	1'43	2'036	182'5	18'1	22'7	3'5	Quick-setting.

Dyckerhoff points out that one of the indications of the figures in this table is that the specific gravity of the cement before ignition is on an average somewhat lower than that of the samples examined by Fresenius in 1884, a result due to the fact that these samples were bought in open market and had absorbed more water and carbonic anhydride than those previously tested, and further to their being, in some cases, at least, slightly underburnt. Merz has pointed out that in the determination of the time of setting of the cement, the practice of using a fixed percentage of water gives rise to errors, inasmuch as each cement should be gauged with the quantity of water proper to it; this view is endorsed by Meyer, Schiffner, and Bohme, who further insist on the large personal equation due to the operator himself.

Durand-Chaye has found that the shape of the test piece has an influence on the result of compression tests. Thus 7 cm. cubes show a strength of 78 kilos. per sq. cm.; prisms of the same section, but 10 cm. long, give a result of 58, and those 30 cm. long one of 50 kilos. per sq. cm.

Erdmenger's high-pressure test (see page 931) is said not only to be suitable for the detection of magnesium cements, but of those unsound from other causes. For example, cements containing too much lime or imperfectly mixed cements in which a portion of the lime occurs as isolated granules (many English cements are said to be of this character) can be detected by its means. An industrial application of the high-pressure method has been suggested, namely, for rapidly maturing articles composed of cement with much inert aggregate such as sand and gravel; for instance a mixture such as 1 part of cement with 10 of sand soon attained considerable strength when exposed to steam at 10 or 15 atmospheres; test pieces of 1 part of cement and 11 of sand, after having been allowed to set for two days and then exposed to steam at 20 atmospheres for 24 hours attained a strength of 13–16 kilos. per sq. cm., while if allowed to harden in the ordinary way they would not have exceeded 4–5 kilos. per sq. cm. at the end of one month.

Some properties of Cement.—The method of cooling Portland cement clinker by means of water or steam, lightens the subsequent labour of grinding by causing a considerable previous disintegration. According to Erdmenger the operation is particularly advantageous in the case of clinker with a tendency to "fall" as it plunged under water even in the very act of falling the change is arrested and hard strong clinker results. Water is preferable to steam, as it acts with greater certainty. He further considers that this treatment diminishes the tendency of such cements to blow, particles of free lime being thereby slaked. As an example of the use of a stream of water the figures in the following table may be quoted.—

	A.	B.	C.	D.
	Per Sq. Cm.	Per Sq. Cm.	Per Sq. Cm.	Per Sq. Cm.
After two days,	4.5	8.3	8.0	9.0
After three days,	5.6	9.4	10.0	11.3
After one week,	8.0	15.0	17.3	17.1
After four weeks,	13.7	22.7	24.1	25.2
After three months,	16.8	28.0	30.6	31.1

Sample A. was cement allowed to "fall"; B. had been subjected to the water treatment; C. had been broken down to a coarse powder by the quenching process; D. a sample of sound clinker similarly disintegrated. In the observer's opinion the changes caused by quenching are analogous to those occurring in the granulation of blast-furnace slag (this Journal, 1890, 863).

Certain experiments were carried out on cement concrete at Ymuyden, some of the results being as follows. The blocks were 1 m. in length and 0.2 m. in width (thickness not stated), and after five days' hardening in the air had been buried in a sand hill. The strength in compression was 7–10 times the strength in tension, a granite aggregate made into concrete with a mortar consisting of three parts

of sand and one of cement, had a strength in tension of 12 kilos. per sq. cm.; clinker concrete gave a result of 10.9 kilos. per sq. cm., while a result of 9.44 was obtained when sandstone was used.

Schiffner catalogues the deteriorating influences to which Portland cement mortar is subjected, under the following heads: (1) the hardening may be hindered by the character of the sand used; or (2) by the action of foreign bodies such as acid liquors and solutions containing tannic acid or the soluble substances present in bricks, or the soil itself upon the cement while in the fresh state. (3) Improper treatment of the cement while being made into mortar, such as working it after setting has begun, or the use of too much or too little water may have a bad effect upon its hardening.

The combination of cement with water takes place *passu* with its hardening. Feichtinger has proved this by the following set of figures:—

Immediately after gauging	0.49
After 4 hours	1.41
After 20 hours	2.29
After 3 days	5.62
After 7 days	6.85
After 14 days	7.96
After 18 days	8.45
After 21 days	8.91
After 24 days	10.40
After 28 days	10.52
After 35 days	11.34
After 42 days	11.35
After 49 days	11.50
After 56 days	11.60
After 80 days	11.56

Schiffner's experiments give figures corroborating those of Feichtinger. The combination with water takes place somewhat more slowly in air than under water. A further series of experiments in which the amount of water provided for the cement was purposely inadequate, showed that under severe conditions the test pieces were weaker than where ample water was present, and that they absolutely disintegrated in some cases. As the quantity of water absorbed by the cement while setting averages 10–12 per cent., it is plain that if the amount of water used in gauging (about 27 per cent.) be prevented from escaping during hardening, more than sufficient will be present to effect the requisite chemical changes; indeed, even with a minimum of 7 per cent. retained during hardening a product of satisfactory strength resulted. The premature drying of the cement is favoured by its exposure in thin layers, by its use with dry bricks, or during the prevalence of a keen wind. The practical deduction that all precaution should be taken to keep cement moist during the early part of its existence is obvious.

Schott has observed in the case of cements which disintegrate when tested dry, that an early sign of mischief is to be found in the formation of sundry small eminences which occur on the lower smooth surface of the pat; a thin crust is easily detached from these spots with the point of a knife and beneath it lies a lightish granule of feeble consistency. Such disintegrated parts often contain as much as 30 per cent. of calcium carbonate.

The circumstance that the cracking of cement in air is effected by the same means as the blowing that occurs under water, has led Tetmajer to believe that the difference between the two phenomena is one not of kind, but of degree. The same experimenter quotes the case of a cement which when stored for two months developed the property of bursting the casks which contained it. Two samples were taken from such a cask, one near the outside, the other from the centre. The cement on the outside complied with all the usual tests, while that from the centre failed when thus tested, beginning to go to pieces after the lapse of six months and eventually becoming completely disintegrated. After exposure to the air for 18 months the test pats from the centre contained 4.77 per cent. of water and those from the outside 6.43 per cent. Either, therefore, they had originally absorbed different amounts of water in spite of similar treatment, or the sample which contained less water originally absorbed as much as the other, but suffered the loss of a portion of it by the action of the carbonic anhydride from the air.

The Expansion of Cement.—Schumann, continuing his earlier researches, has shown that a prism 10 cm. long, composed of one part of cement and three of normal sand increases in length on an average 0.0088 mm. in one week and 0.002 mm. in the next three weeks. The following results were obtained with various cement materials, the test pieces being kept in water for the first week and for the remaining three weeks in air:—

		Mm.
Portland cement A.	1 cement, 3 sand	0.0400
Portland cement B.	1 cement, 3 sand	0.0405
Portland cement C.	1 cement, 3 sand	0.0410
Portland cement D.	1 cement, 3 sand	0.0455
Hydraulic lime	1 lime, 3 sand	0.0540
Puzzuolana, 1	1 cement, 3 sand	0.1050
Puzzuolana, 2	1 cement, 3 sand	0.1100
4 trass, 3 lime, 2 sand		0.1330

Further discussion has occurred concerning the failure of the cement on Stephans-dom (this Journal, 1889, 781). Schott has examined two samples taken therefrom, one of which was a dense, hard, grey mass, the other yellowish-grey, soft, reticulated with cracks, and considerably laminated. The analyses of these samples showed a considerable difference in respect of the amount of carbonic anhydride and water that they contained, the grey containing 14.8 per cent. of the former and 11.4 per cent. of the latter, while the lighter samples gave the figures 24.5 per cent. and 9.0 per cent. When calculated back to the original cement, the composition of the samples showed them to be of identical origin. From these results Schott arrives at the following hypothesis:—Cements used 30 years ago contained a considerable amount of underburnt material. When such a cement is brought into contact with a considerable excess of water the heavily burnt part sinks to the bottom, while the lighter floats, and thus two layers of different quality are formed. This is borne out by the amount of lime combined with carbonic anhydride in the two samples, 18.8 per cent. out of a total quantity of 42.8 per cent. being thus united in the hard sample (less than one-half the possible amount) and 33.7 per cent. out of 36.2 per cent. in the soft yellowish sample (*i.e.*, 95.7 per cent. of the total lime).

According to Dyckerhoff, all cement, even well-burnt, if used neat and exposed to weather influences, is apt to form shrinkage cracks which permit the entrance of water and carbonic anhydride, and would account for many of the phenomena observed in the case of Stephans-dom.

Miscellaneous Observations.—Goslich calls attention to the fact that lead pipes and zinc channels imbedded in Portland cement are considerably attacked, a result due to the alkalinity of the cement, in Laube's opinion. Seger points out that the zinc used in a building in Berlin for which stone containing sulphates had been employed, was corroded where it came in contact with the latter (this Journal, 1890, 1037). Lieven states that iron imbedded in cement exfoliates, a result which he attributes to the presence of sulphur in the cement. Delbrück, on the contrary, recommends the preservation of steam boilers from rust, when they are set in damp masonry, by the interposition of a layer of cement.

Some facts concerning "floating cements" are given by Goslich. Certain cements mix with difficulty with water, and even after admixture has been effected the mass is lumpy and sets badly. This condition appears to be due to the presence of a small quantity of oil. "Floating cement" cannot be produced by merely triturating cement and oil together at the ordinary temperature, but may be obtained by heating cement to 40°–50° C. previous to the addition of the oil. That the explanation is correct appears probable from the fact that floating cement gives off an empyreumatic smell on heating, and then has no further tendency to float. The oil causing this peculiar behaviour is generally derived from the lubrication of the grinding machinery, but not

invariably so. Cement taken direct from the stone-breaker and ground in a porcelain mortar has been known to float, the oil in this case having been derived from the fuel.

Dyckerhoff has made a series of experiments bearing on the question of the influence of magnesia on cement, the results of which have been already given briefly (this Journal, 1890, 1037). The composition of the mixtures used is shown by the following table:—

	(1.)	(2.)	(3.)	(4.)	(5.)
Insoluble residue	0.7	0.17	0.70	1.14	1.41
Fe ₂ O ₃ + Al ₂ O ₃	10.74	10.25	10.54	9.37	8.67
CaO	62.50	59.12	55.14	50.56	47.28
MgO	1.93	6.23	11.36	17.80	21.14
Loss on ignition	0.8	1.24	1.11	1.16	1.50
SiO ₂	21.46	20.48	19.42	18.31	18.71
Specific gravity	3.159	3.169	3.219	3.251	3.251

The mixtures were the more refractory as the percentage of magnesia (and indeed the total basicity of the mixture) increased. The specific gravity rose in a corresponding manner. The attainment by the samples of their full strength and their subsequent retrogression are shown by the curves of the following table:—

CURVES SHOWING ACTION OF MAGNESIA ON CEMENT.

As will be seen, the sample containing 1.93 of magnesia showed a regular increase in strength; the remaining five cements retrograded after six months. The retrogression was retarded but not prevented by heavy burning. The expansion of the six cements is shown in the following table of curves (see next page).

Taking the case of the cement with only 6.23 per cent. of magnesia, the continued increase of its expansion is notable when compared with normal cement. Although this expansion might not be dangerous when the cement was used with a large amount of inert aggregate, yet it might easily be objectionable in "fat" mixtures.

Dutoit has made experiments on the influence of the size of grain of the sand on the hardening of cement. It appears that the use of coarse sand gives a stronger product for mixtures of 1:4 and 1:5. Further experiments confirmed the well-known fact that coarse sharp sand gives a higher strength than small rounded sand. Moreover, the permeability of mortar made with coarse sand is lower than with fine; the reason for this is that the quantity of water used

ingering is smaller, and also that the cement occupies about five-sixths of the space left by the sand instead of only two-thirds.

CURVES SHOWING EXPANSION OF CEMENT BY INFLUENCE OF MAGNESIA.

Journet has examined the behaviour of cement gauged with salt water at low temperatures (compare this Journal, 1889, 393). He obtained smaller tensile strengths than when working under normal conditions, but this might well be due to the low temperature rather than the salt water hindering the hardening of the cement.

The addition of soda to cement mortar has been proposed by Bernhofer to aid the hardening of cement exposed to frost, but the suggestion must be received with some reserve until corroborated by further experiment.—B. B.

Proceedings of the Association of German Cement Makers. Fourteenth Annual Meeting, 27th and 28th February 1891.

The first matter of importance was the announcement that the limits for Portland cement laid down by Fresenius, some years ago, as the result of an investigation undertaken on behalf of the Association, had been definitely abandoned as valueless, and omitted from the section on testing cement of the work about to be issued under the auspices of the Association.

The report of the committee on improved methods of testing was received and discussed; the chief points of interest being—

1. Investigations as to the possibility of substituting Sieves made of Metal Plate with circular Holes for those of Wire hitherto used, for the preparation of Normal Sand.

The reason for the suggested change was that the size of the hole resulting from the crossing of wires, as in an ordinary sieve, is liable to vary on account of the displacement of the wires in use, an inconvenience avoided by the adoption of the proposed perforated plate. Experiment, however, showed that it was impossible to construct sieves of this kind which gave a sand identical with the normal sand prepared by means of the standard wire sieves at present in use. Although the sand thus differed, test pieces made with it gave results nearly identical with those obtained with normal sand. A certain discrepancy was observed by Delbrück, while Dyckerhoff found almost no variation, but in all cases the differences were not large. The latter experimenter also communicated figures obtained with Froenwäde sand and Rhine sand, showing but little

divergence. Tomei also communicated some results which are recorded in the following table:—

Cement.	Days.	Strength in Tension. Cement 1: Sand 3.		Strength in Compression. Cement 1: Sand 3.	
		Kilos, per Sq. Cm.		Kilos, per Sq. Cm.	
		Normal Sand.	Plate Sieves.	Normal Sand.	Plate Sieves.
			0.7. 0.6.		0.7. 0.6.
A.	7	16.6	18.0	18.4	136.8 142.8
	28	21.3	22.9	22.9	204.6 216.0
B.	7	13.1	14.4	14.6	103.6 97.8
	28	16.1	15.5	15.9	176.4 174.0

The chief objection to the new form of sieve lies in the fact that it soon becomes blocked, and is cleaned with difficulty. The general opinion was therefore against its adoption, but the suggested use of wire sieves with 64 and 144 meshes per sq. cm., instead of those with 60 and 120, met with little opposition, no important alteration in the character of the product resulting from the change.

2. The Influence of the presence of Magnesia in Cement.

The commission appointed to examine into the question consisted of Dyckerhoff, Schott, and Arendt. A difference of opinion as to the way in which the work of the commission was to be carried on arose, and the conclusions arrived at are accordingly recorded separately. Dyckerhoff, in continuance of former work (this Journal, 1890, 1037; also page 929), has made further experiments with cement containing 1, 3, 4, 5, 6, and 8 per cent. of magnesia, which proved that those containing 4 per cent. and over showed expansion after one year, increasing with the proportion of magnesia, the expansion being greater in the time included between the end of the first and the twelfth month than in the first month, a result precisely the reverse of that obtained with normal cement. Even with as little as 5 per cent. of magnesia, the strength decreased after one year. The retrogression in strength and the tendency to show cracks developed very slowly, particularly in specimens kept in air instead of water. Even in the latter case two or three years often elapsed before cracks became apparent. In consequence of this, Dyckerhoff rejected the conclusions of Schott as to the reliability of cements containing magnesia based on observations extending over only four months. He also dissented from Erdmenger's view that such cements can be detected by the high-pressure steam process of the latter (compare this Journal, 1890, 511) on the ground that other cements containing a normal percentage of magnesia similarly disintegrate or decrease in strength. He demurred to Arendt's statement that certain tests carried out by Bauschinger proved that cements containing as much as 7.15 per cent. of magnesia expand no more than do normal cements, because of the expansion of one of the cements used for comparison being altogether abnormal in spite of the fact that it was otherwise normal.

Arendt objected to this conclusion, considering that the cement in question (which was of the well-known "Stern" brand) should be included in the comparison, in which case the magnesia cements could not be condemned out of hand.

Schott pointed out that the raw materials used by Dyckerhoff had been passed through a sieve with only 900 meshes per sq. cm., whereas the commission had used one with 1,600 meshes, and considered the failures observed with cements made with the former, due to the comparative coarseness of their raw materials preventing sufficiently intimate admixture. He further contended that the cements used in the law courts at Cassel, the failure of which was the immediate cause of the resurrection of the magnesia question, was not true Portland cement at all,

not even a magnesian Portland cement. It was made from a natural deposit of mixed chalk and clay, similar to many other cement stones, and far from intimately mixed, pieces of limestone as big as peas being scattered throughout the mass. On burning, this limestone became converted into caustic lime, and inevitably caused considerable blowing. This was demonstrated at the meeting by the exhibition of a piece of the material containing a fragment of eale spar. The extreme importance of the proper admixture of the raw material was proved by experiments made on the cement stone in question, which had been (1) burnt direct, (2) burnt after powdering and passing through a sieve having 1,600 meshes per sq. cm. When tested by Bauschinger's expansion apparatus, the former showed an expansion of 543 (expressed in $\frac{1}{1000}$ mm.), while the latter gave a result of only 16, the time in both cases being 14 days,—a difference amply sufficient to account for the blowing observed. To this view Dyckerhoff objected, on the ground that expansion caused by the presence of free lime would show itself soon after the cement had set, whereas that of the cement at the law courts of Cassel became evident after a longer lapse of time.

Meyer called attention to the fact that the composition of cements rich in magnesia might easily exceed the limits laid down by Le Chatelier's equation, $\frac{\text{CaO} + \text{MgO}}{\text{SiO}_2 + \text{Al}_2\text{O}_3} = 3$, and in consequence such cements would inevitably blow. He considered that the analytical difficulties encountered in the determination of magnesia in cement were great, and in the event of a limit being fixed, a method should also be prescribed. That some such difficulty is apparent to German chemists, is shown by a communication by Prüssing, who sent two portions of a well-mixed sample to two Government testing stations, with the result that the percentages of magnesia returned differed by 30 per cent. of the amount of the smaller from each other. The net result of the discussion as regards any proposed alteration of the permissible percentage of magnesia was negative, the quantity which was considered harmless being taken as $3\frac{1}{2}$ per cent., but no definite ruling that amounts in excess of this were injurious being made.

3. Rapid Methods for ascertaining the Soundness of Cement.

Schumann stated that he considered the rules already in use sufficed to discriminate between sound and unsound cements (the crucial test adopted by the Association consists in the observation of the behaviour of a pat kept in water for 28 days). Rapid tests depending on the exposure of the cement to a temperature higher than that which it would have to encounter in practice, sometimes condemned a sound cement (contrast Le Chatelier's opinion on this point, this Journal, 1891, 255), but had the advantage of detecting free lime. On the other hand, inferior cements, poor in lime, might pass them without condemnation. With regard to Erdmenger's high-pressure test (subjecting test pieces to the action of steam at 10–20 atmospheres), it was too troublesome ever to come into extended use. The method of exposing the cement to the action of a water-bath at an elevated temperature had the objection that small fluctuations in the temperature caused considerable variations in the results, and moreover the right temperature and time of exposure were at present undetermined (this Journal, 1891, 255). He considered that though tests of this kind might be useful for manufacturers, yet the test prescribed in the rules of the Association (*v.s.*) was the only one which would prove free from ambiguity for the consumer. Schiffner pointed out that the normal test occasionally failed, inasmuch as pats which had remained perfect when kept under water for 28 days were nevertheless so far from sound that they went to pieces afterwards when exposed to air, a statement corroborated by Schott, who had observed a similar phenomenon. The chemical composition of cement showing this property had unfortunately not been determined. According to Schott, the occurrence is rare, and only takes place with cements that are quite fresh; aëration prevents it.

Heintzel, Schumann, Schott, and Dyckerhoff called attention to the fact that pats of neat cement when removed

from water and dried rapidly sometimes showed cracks from mere shrinkage and not from unsoundness; the tendency of Portland cement when used neat on the large scale and freely exposed to drying influences, to develop cracks, was due to the same cause. According to Dyckerhoff, this tendency is more marked the finer the cement is ground, and the more water it therefore takes up in gauging. The sense of the meeting on the matter was summed up by the president, Dr. Delbrück, as follows:—

That no results had been advanced invalidating the normal test, and that the various quick tests for soundness that had been proposed, though useful to the maker to check the process of manufacture, were not suitable for basing the decision of the consumer upon.

4. Erdmenger's High-Pressure Test.

The process consists, as mentioned above, in exposing test pieces of a mixture of sand and cement to a steam pressure of 10–20 atmospheres.

With some samples, a high tensile strength is attained in a few days or hours, even when the mixture is poor in cement. An amount of magnesia equal to 11 per cent. in the cement itself is detectable by the tendency to blow observed, and in Erdmenger's opinion, 5 per cent. is as high as it is safe to go. His experience, extending over 12 years, has led him to believe that the presence of any considerable amount of magnesia can always be detected by this test. In judging a cement by this method it must be remembered that the blowing of a cement containing much magnesia, but otherwise sound, is not apparent in mixtures poor in cement, owing to the greater space afforded by the inert aggregate for the expansion of individual particles. The destruction of a cement or its attainment of a low tensile strength when tried by the high-pressure test, may proceed from other causes than the presence of magnesia.

The following are some results obtained by the test:—

- (1.) Cement A.—Neat test pieces much increased in volume, but free from cracks and fairly resistant; tensile strength of sand tests 9 kilos. per square centimetre.
- (2.) Cement B.—Neat test pieces much swollen and very friable; tensile strength of sand tests 11 kilos. per square centimetre.
- (3.) Cement C.—Neat test pieces strongly swollen, very friable and much cracked; sand tests in a similar state.

The magnesia in these samples amounted to 2, 4, and 7 per cent. respectively.

In the course of the discussion upon the question of the quantity of magnesia permissible in cement, it was stated that the limit adopted officially in Russia would in future be 3 per cent., though 5 per cent. was allowed until the end of the present year.

5. The Monier System of Building Construction.

Toméi read a communication dealing with the above system of building. It had its origin in the desire of Monier, a Paris gardener, to obtain flower tubs stronger than wood and less weighty than artificial stone. He therefore used a framework of iron covered with cement mortar. The development of the system is largely due to G. A. Wayss. The low tensile strength of cement is supplemented by the high tensile strength of the iron. The method as usually carried out consists in forming a framework of iron rods 5–25 mm. in diameter, enclosing it in a wooden mould of appropriate shape, and filling in the interstices with a mortar consisting of three parts of sand to one of cement. The iron part of the structure is only held together by thin wire, the adhesion of the cement to the iron, which, according to Bauschinger, amounts to as much as 40–47 kilos. per square centimetre, sufficing to give strength to the structure. Bauschinger also finds that the difference of the coefficient of expansion of the cement and the iron is not so great as to overtask the elasticity of the former. The material is suited to the construction of roofs, cellars, and vaults, especially where it is required that the building shall be fireproof. Its excellence in this respect has been proved by actual experience. A list of

important buildings in which it has been employed is given. An experimental bridge of 10 m. span having proved successful, others of larger size, up to 42 m., have been constructed with a similar result. It has been also found suitable for water tubes and tanks. A tube 2 m. in diameter and 100 mm. in thickness first showing cracks when subjected to a strain of 12,000 kilos. per sq. m. It allowed but little water to percolate through it under a head of 7.5 m. The piece of work which is at once the oldest and most important that has been executed on the Monier system is a water course in Offenbach 1.5 m. in inside width and 1,000 mm. in length, which dates from 1886. Water reservoirs and gas-holder pits have been made by this method in large numbers.

Dyckerhoff, in criticising the paper, related experiences tending to show that if cracks appeared in the cement, water and air would obtain access to the iron, resulting in its corrosion and ultimate destruction, and considered that the use of the Monier system should be confined to structures not exposed to the weather.—B. B.

Practical Observations on the Preparation of Weather-Proof and Water-Tight Coatings for Buildings. T. Koller. *Abstr. Proc. Inst. Civil Eng.* **105**, 1891, 5, and *Glaser's Annalen f. Gewerbe. und Bauwesen*, Aug. 15, 1891, 79.

In 1883, in consequence of the upsetting of a vessel containing kitchen salt, a workman, in order to conceal the effects of the accident, brushed up some of the spilled salt into his whitewash pail, the result was the production of a wash as hard as cement, and which could not be removed by scrubbing. The author considers that this is due to the hygroscopic action of the salt, which absorbs water and permits of the speedy combination of the lime with the carbonic acid of the atmosphere. A trial of this composition upon the brick wall of a well-hole or shaft for light, in which case it was applied with a syringe to save scaffolding, stood extremely well, and after the lapse of four years the coating was as good as ever. The use of three parts of quicklime to one of common salt is recommended.

On the use of paraffin and water-glass, the latter of which has latterly lost all credit in the building trade, it is pointed out that a solution of melted paraffin in three parts of heavy coal tar oil, kept fluid while being applied by immersion of the containing vessel in hot water, forms a most excellent wash or paint for buildings very much exposed to atmospheric influences.

For the successful employment of water-glass, two conditions are essential, the stucco must be uniform in texture very hard and very thin, and the solution must not be applied while the plastering is "green," for in that case the calcium hydrate at once decomposes the silicates. Sufficient time must be allowed for the combination of the atmospheric carbonic acid with the free lime. The water-glass may be used as follows:—10 parts of sharp dry sand, 4 parts of air-slaked lime, 2 parts of chalk or pulverised limestone, and soda water glass of 33 B. are taken. The sand, lime, and chalk are first passed dry through a sieve, and the ingredients are then mixed with the water-glass, diluted with twice its weight of water into the consistency of mortar, and used as a setting coat over the wall-surface to be protected. This coating, in the course of a day or two, sets as hard as a stone, and may then be repeatedly saturated with dilute soda water-glass. Various other recipes are given for coloured solutions, and for varnishes or lacquers to serve as coatings for paper and felt roofings.

PATENTS.

A Process for Manufacturing from Roman Cement a Composition similar to Portland Cement. C. von Fonell, Brunswick, Germany. *Eng. Pat.* 11,398, September 12, 1890, 4d.

The process patented consists in adding slaked lime to Roman cement or hydraulic lime in such proportion that the ratio

of the total lime to that of the total silica, alumina, and ferric oxide is about 1.7. Granulated, dried, powdered, blast-furnace slag, may be substituted either wholly or partially for slaked lime. The advantage claimed is that a material similar to Portland cement may be produced with small expenditure of fuel, seeing that it is necessary only to burn a portion of the ingredients, namely the Roman cement or hydraulic lime, and that moreover at a lower temperature than is needful in the case of Portland cement.—B. B.

Improvements in the Manufacture of Fire-Proof Plastic Material for Cement; also applicable to Smelting and various other Useful Purposes. R. Stone, London. *Eng. Pat.* 16,789, October 21, 1890, 6d.

GRANITE, slate, shale, lava, marble, clay, or analogous materials are mixed with a "flux" such as "petroleum spirit, petroleum, or vitriol, or oils of an inflammable nature" in the proportions of 1 cwt. of flux to 1 ton of the granite, &c., burnt and ground, preferably hot. About 12.5 per cent. of sodium silicate may be added, with or without the addition of 5 per cent. of lime. The material is shaped by moulds while fused, or in a plastic state, and may be used for general structural purposes. "The aforesaid process will also have the effect of removing any metals which may be found in the materials such as iron, gold, lead, copper, zinc, tin, which can be run into moulds or dies, it being injurious to cement." The material may be ornamented by glazing.—B. B.

X.—METALLURGY.

Experiments in Desilverisation by Means of Zinc. H. Rosler and B. Edelmann. *Berg-und Hüttenmännische Zeit.* 1891, 123—125, and *Eng. and Mining J.* May 16, 1891, 582. (See also this Journal, 1890, 1130—1134, and 1891, 550.)

The authors found that upon further trials with Mazarron lead in larger quantities, the method employed in which all the zinc was stirred into the red-hot lead, saturating it as far as possible, gave unsatisfactory results, in spite of the use of aluminium-zinc. The high temperature and the necessary stirring, even if only briefly kept up, caused a heavy oxidation as before, while the main skimmings, forming not less than 15 per cent. of the total weight were entirely oxidised, so that it was out of the question to melt out an alloy; on an average the silver contents did not exceed 1 per cent. Thus the result showed scarcely any advantage whatever over the usual method of desilverisation.

As in all the experiments success had proved to depend on avoidance of all oxidation during the process, the authors were prompted to repeat the whole series, since they had succeeded in the subsequent work, by means of improved heat-measuring apparatus, in controlling the temperatures with greater precision and in dispensing with some of the zinc, thus reducing the time of the operation.

The object of these experiments was, as before, to avoid the formation of any zinc scum whatever, in the ordinary meaning of the word, and to segregate a zinc-silver alloy which should contain all the silver, not more than four parts of zinc for every part of silver, and be fit for electrolytic or other rational method of treatment. Sufficient inducement to continue the experiments was, however, held forth by the prospect, alone, of conducting the desilverisation in such a manner as to lessen the time, save zinc, fuel and labour, and obtain directly a skimming with 3 per cent. and upward of silver, besides dispensing with liquation.

To determine the temperatures of the molten lead baths, the authors used Dr. Alefeld's method, whereby temperatures of even more than 500° C. can be measured by means of a quicksilver thermometer filled with nitrogen. This is not used in direct contact with the bath, but is suspended in a sheet-iron flask which is immersed up to a marked line in the lead bath, thus allowing the air to circulate around the bulb. The Wiborgh pyrometer, which is placed directly in the bath and is particularly adapted for measuring temperatures obtaining in these experiments, invariably gives higher readings than the quicksilver thermometer just described, the difference increasing with the rise in temperature, and amounting here to between 70° and 110° C. This pyrometer, however, can be dispensed with when a scale of difference has once for all been provided, the readings of the nitrogen thermometer being sufficiently accurate up to about 500° C. This substitution has the advantage that any labourer can at any time ascertain the temperature. For these experiments the following scale was used:

	°	°	°	°	°	°
Wiborgh's.....	330	360	390	420	450	480
Quicksilver.....	260	285	310	334	357	379

The object in view can, as proved by the experiments, be best attained if the necessary zinc, in the form of a concentrated solution in lead, is poured red hot into the less hot lead bath and stirred only very briefly; or still better, if this zinc solution be passed from below into the argentiferous lead, which has a temperature of about 500° C.; or if the latter be poured into the red-hot zinc solution with no stirring whatever. In that case, the zinc remaining dissolved and no longer able to separate out and rise, is uniformly distributed through the entire lead bath, combines with all the silver, and when cooling carries this with it to the surface, forming skimmings which are rich in silver, contain very small quantities of oxides, and hence can easily be liquated and smelted out. The first experiment, performed on a small scale, following this plan, was made with impure lead of commerce and proved a complete success. 10 grms. of aluminium-zinc were melted in the bottom of a small iron crucible, and when it became red hot, 250 grms. of silver-lead in small lumps were gradually thrown in, so that the mass constantly remained at red heat; afterwards the temperature was kept unchanged for some time, and the crucible slightly shaken once in a while, but stirring was avoided in order to decrease the danger of burning the zinc; finally the mixture was added to 750 grms. of silver-lead, melted at 500° C. After gradually cooling and removing the scum, the residual lead proved free from silver. Thus, Spanish argentiferous lead containing about 1,500 grms. per ton was completely desilverised by a single addition of 1 per cent. of zinc, with no stirring and almost entire absence of oxidation.

For the saturation of the zinc at a red heat, it is desirable to use the lead which, in the previous operation, came out of the bath as the last part of the skimming, as that lead taken from the bath when the latter is quite cooled is least liable to be oxidised, and, besides, is rich in zinc, poor in silver, and also free from copper, which last, if present, promotes the oxidation in the red heat. The results of this experiment were as follows:—

	Grms. Silver.
100 parts of lead were melted with	159
Added 1·6 parts of fresh zinc.	
0·6 „ zinc from last skimmings with	50
1·6 „ zinc with	200
Skimmed (1) 0·5 parts of zinc with.....	150
(2) 0·5 with.....	50
Remained 0·6	—
1·6 parts of zinc with.....	200

200 kilos. of pure argentiferous lead worked on this plan gave first skimmings that contained 4 per cent. silver and were not at all oxidised, so that they could be very well

liquated, and, under the application of salt slags, melted into a silver-zinc alloy with 20 per cent. of silver. The solution of zinc in lead, for which purpose the last skimmings were used, was also highly successful.

The only thing remaining, then, was to try the method with the impure silver-lead of commerce, and here, too, the result with quantities of 200 kilos. was favourable in contrast to the previous experiments on the unimproved plan; the first skimmings were relatively rich and only very slightly oxidised, and the lead was entirely desilverised. Thus, it seems scarcely subject to doubt that this method may be introduced to advantage into industrial works. It requires no essential changes in the usual arrangements in desilverising works; it saves in time, fuel, labour, and zinc, gives rise to fewer by-products, and makes it possible to regain more zinc than before.

Coal in the Lead Blast Furnace. Arthur S. Dwight. Eng. and Mining J. 1891, 162.

It may be interesting to note the results of an experiment to replace coke with anthracite in a lead blast furnace. The credit for this experiment is due to Alfred Ropp, at present connected with the Selby Smelting and Lead Company, of San Francisco.

In 1887, while Ropp was in charge of the Tomichi Valley Smelter, at Gunnison, Colo., the supply of Crested Butte coke got very low. Some selected anthracite, of about goose egg size, from the neighbouring mines of Crested Butte, was on hand in the works, and as coke was very dear, he decided to try replacing some of the coke on his charges with this anthracite. It is important to note that no charcoal was used. Ten per cent. of the coke was first replaced with anthracite. The smelting capacity of the furnace was slightly reduced: the slag, however, remained clean, i.e., it carried 0·4 per cent. to 0·8 per cent. lead and was low in silver. The percentage of anthracite was gradually increased until 60 per cent. of the original charge of Crested Butte coke had been replaced with anthracite. The smelting capacity of the furnace diminished as the proportion of anthracite increased. The slag remained about the same in lead and silver, likewise the matte, the latter containing about 8 per cent. lead and 4 per cent. copper.

During the whole of the experiment the speiss was of the coarsely crystalline variety, showing that plenty of iron was reduced. The top of the charges remained cool and the crucible free. The tuyeres seemed to darken and get somewhat harder as the percentage of anthracite was increased. There was about 7½ per cent. of zinc in the charge during the experiment, but it seemed that less zinc accretion was formed on the walls than when coke alone was used. As to the manner of feeding, the charges of ore and fluxes and the fuel charges were distributed in even layers over the whole section of the furnace.

The experiment lasted 12 days, and at length when 60 per cent. of anthracite was used the capacity of the furnace was decreased one-third.

Under the conditions prevailing at Gunnison, particularly on account of the high cost of labour, the experiment was not a commercial success. The furnaces employed were water-jacketed furnaces 80 in. × 37 in. in section at the tuyere level, and 9 ft. from tuyeres to feed floor. Had they been higher it is very likely that the results might have been better. Another condition that made the furnaces run more slowly was the extreme fineness of the charges, which became more and more effectively troublesome as the coke was cut down.

In both of the experiments, one with bituminous coal and one with anthracite, there are several advantages that command notice: (1) Cool tops; (2) open crucibles; (3) good reduction, with clean slags and mattes low in lead; (4) less zinc accretions.

The fact that Ropp used no charcoal and worked with a very low furnace and a charge less coarse than the average, should be borne in mind, in comparing the results of the two experiments.

The common points of advantage demonstrated in both cases are of sufficient importance to justify very extended experiments by lead smelters with the use of coal in their shaft furnaces.

The Siemens Furnace. R. Addie. A Paper read before the City Analysts' Society, Glasgow. Engineering, 1891, 52, 103—104.

AFTER describing the ordinary open-hearth Siemens furnace, the author gives analyses of the silica blocks, bricks, &c., used for its lining, which are appended below:—

	Rehmon Silica Blocks.	Glenboig Silica Bricks.	White Sand.
Silica	96.72	96.16	96.22
Alumina	1.50	1.96	1.64
Oxide of iron ...	1.36		
Lime	Trace.	1.88	Trace.
Magnesia	Trace.	Trace.	Trace.
Combined water	2.14
Total	99.58	100.00	100.00

The furnace bottom is put in by placing a layer of ganister and fine fireclay, often mixed with powdered silica bricks, upon a layer of brick resting upon the top of the cast-iron plates which form the lowest point of the melting chamber. The furnace is then heated up until this is dry and the true bottom put in, consisting, in the acid process, of the white sand of which the analysis is given above, mixed with a certain proportion of red sand, which, containing rather more iron, alumina, and magnesia, is less refractory than the white, and acts as a binding material. The usual process of making Siemens steel with pig iron, scrap, and iron ore is described, and analyses are given of the producer-gas as it leaves the producer and at the bottom and top of the regenerator. The chief points shown by these are that the methane has been partly decomposed by the heat to which it has been subjected, and the percentages of hydrogen and carbonic acid have been slightly increased; the changes are, however, so small that for practical purposes it may be considered that the only alteration the gas has undergone is its rise of temperature.

The chemical changes occurring during the operation are thus traced. During the first process of melting the pig iron and scrap together, $\frac{1}{3}$ of the silicon and about $\frac{1}{4}$ of the manganese are oxidised; $\frac{1}{3}$ of the carbon is also oxidised, while the remainder of the graphitic carbon combines with the iron. On adding the ore, the manganese and finally the rest of the carbon and silicon are oxidised. The appearance of the bath on the addition of the ore is described as follows:—The surface of the charge froths up, and reddish fumes, due to the oxidation of the manganese, are given off. The frothing recurs on adding more ore, and when the charge is "coming through the boil" the surface of the molten mass begins to circulate from the cooler to the hotter end. When the manganese is high, as in Scotch pig, longer time is taken and more ore used before the charge boils than when pig poor in manganese, such as is made from Cumberland ores, is employed. The process of oxidation previous to and during the boil therefore takes place as follows:—

1. Most of the manganese is oxidised in the stage known as "coming through the boil," and all of it is oxidised before boiling actually takes place.
2. Most of the silicon is oxidised, forming silicates.
3. No carbon is oxidised until the boil is thoroughly begun.

The following analyses show the composition of the metal when coming through the boil and when the boil is completed:—

	Per Cent.	Per Cent.
Carbon	1.655	0.155
Silicon	0.196	0.004
Sulphur	0.022	0.024
Phosphorus	0.043	0.048
Manganese	Nil.	Nil.
Iron (by difference)	98.082	99.769

After the completion of the boil a sample is taken, tested chemically and mechanically, pig iron added if necessary to raise the percentage of carbon, and finally ferromanganese to deoxidise the metal and remove sulphur. The effect of the manganese is also to remove slag from the molten steel and neutralise to some extent the bad effects of phosphorus. Silicon is also sometimes added, in the form of silicon pig, to quiet the metal in the ladle. The final composition of the typical charge quoted would be as follows:—

	Per Cent.
Carbon	0.170
Silicon	0.004
Sulphur	0.023
Phosphorus	0.048
Manganese	0.346
Iron (by difference)	99.409

Process for Utilising Zinc-Blende Fume. Krause, Berg. und Hüttenm. Zeit. 1891, 246, and Abs. Proc. Inst. Civil Eng. 105, 1891, 56—57.

THE fume from zinc-blende roasting containing sulphate of zinc and iron have not until lately been successfully recovered, although suggestions and experiments have not been wanting.

Some years ago the fume from smelting works on the Rhine was leached in water and the solution treated with lime, the zinc being thus precipitated as hydroxide. Profitable results, however, were not obtained by this method, *firstly*, because the precipitation was imperfect, and *secondly*, because the lime was very destructive to the furnaces.

A new process, patented by G. Krause, of Cöthen, has achieved better results. It consists in leaching the fume in water and precipitating by sodium carbonate or similar agent, producing an artificial calamine containing 45—50 per cent. of zinc. Lots of 1,000 kilos. are leached, preferably hot, and sodium carbonate is added in excess. The mixture is filtered, and the filtrate contains, besides the zinc and iron carbonates, sodium sulphate. The Glauber's salt can be recovered by treatment with sulphuric acid and evaporation. The remainder is dried at the ordinary temperature, calcined, and smelted.

1,000 kilos. of fume containing 11 per cent. of zinc, 2 per cent. of iron (both in form of sulphate), gave 200—250 kilos. of calamine, containing 45—50 per cent. of zinc and 260 kilos. of anhydrous Glauber's salt.

190 to 200 kilos. of sodium carbonate was used, the cost of which was covered by the production of the Glauber's salt.

A modification of this method is to treat the leached fume with barium nitrate, causing the formation of a barium sulphate, which is marketable as blanc fixe. The calamine is formed by sodium carbonate, potassium carbonate, or ammonium carbonate. The filtrate will also contain ammonium nitrate, which can be recovered by evaporation. 1,000 kilos. of fume, containing 11 per cent. zinc and 2 per cent. iron treated in this way gave 200—250 kilos. of calamine, 475 kilos. of blanc fixe, whilst 350 kilos. of potassium nitrate (Chili saltpetre), 350 kilos. of barium nitrate, and 260 kilos. of carbonate of soda were consumed.

PATENTS.

Improvements in the Manufacture of Steel. J. F. Hall, Sheffield. Eng. Pat. 14,658, September 17, 1890. 4d.

An electric current is passed through molten iron or steel, either during or after casting, in order to "induce the molecules to arrange themselves in such a manner as to condense and consolidate the metal." The current may be passed by fixing one electrode in the bottom of the mould, whilst the other is held in the stream of metal issuing from the ladle.

—H. K. T.

An Improved Powder suitable for Use in Coating the Interior of Steel and other Moulds. D. Stephens, Kidwelly. Eng. Pat. 16,549, October 17, 1890. 4d.

A SILICIOUS rock known as "Dinas" silica stone and containing about 98 per cent. of silica, 1 per cent. of alumina, 0.5 per cent. oxide of iron, and 0.5 per cent. of lime, is washed and calcined. The stone is then ground until of the consistency of wheat-flour, contact with metal being avoided in the grinding. Sometimes 0.5 per cent. of aluminous clay is added. The above powder is mixed with water or sour beer and used as a lining for steel or other moulds. It is preferably toughened by coating with tar and firing. When used for green mould steel coatings the paint is dusted on the mould out of a coarse bag.—H. K. T.

Improvements in Refining Copper. J. C. Bull, Erith. Eng. Pat. 17,173, October 27, 1890. 8d.

In the purification of copper by the Bessemer process the heat furnished by the combustion of the impurities is not sufficient to maintain the metal at a suitably high temperature. In order to secure this high temperature the patentee introduces an oxidising substance, such as Chili saltpetre, into the molten metal. This is effected by providing a cavity at the bottom of the converter in which the nitrate is placed, and which communicates by perforations with the body of the condenser. When the molten metal is poured into the converter, some of the metal finds its way through the perforations into the cavity beneath, and the heat from the metal decomposes the nitrate and causes a stream of oxidising gases to rise through the metal in the converter. Or the nitrate in a fused state may be forced by air pressure into the perforated cavity. Or, lastly, an ordinary Bessemer converter may be used, the nitrate, in a powdered state, being supplied by an automatic feeding arrangement to the current of air. The converter is lined with ganister, or a mixture of sand and clay, and the metal is covered with a suitable silicious slag.—H. K. T.

Improvements in the Separation of Gold from Ores or Materials containing it. W. D. Bohm, Aeton. Eng. Pat. 18,235, November 12, 1890. 8d.

In this process the crushed and roasted ore is mixed with dry bleaching-powder, and is placed in a vat provided with a false bottom. Dilute sulphuric acid is then continuously pumped through the ore until the gold is extracted. It is then precipitated in the usual way. Instead of the above combination of bleaching-powder and acid, a solution of chromine ($\frac{1}{8}$ to 2 per cent.) in water may be circulated through the ore. Or the latter may be soaked with nitric acid and hydrochloric acid pumped through it. A combination of leaching vat, force pumps, and waste chlorine absorber is described in the specification.—H. K. T.

Improvements in the Manufacture of Iron and other Metals, and Apparatus therefor. J. Y. Johnson, London. From A. Imbert and G. Jullien, Lyons, France. Eng. Pat. 19,734, December 3, 1890. 8d.

POWDERED iron or other metallic ore mixed, if necessary, with suitable fluxes, is reduced with gaseous fuel in a rectangular furnace. The spongy mass is then allowed to

fall into a mould, fresh ore taking its place. The spongy metal is then pressed into an ingot or bloom. These blocks or blooms are now ready for treatment in a Martin furnace, or for other manufacturing process. The mode of production enables purifying agents to be added such as would be required in a subsequent treatment in a Martin furnace, or the ingot may be reheated and hammered or rolled. A combination of furnace, press, &c. is described in the specification.—H. K. T.

Improvements in Process and Apparatus for Procuring Cyanogen and its Compounds from Gases. H. H. Leigh, London. From J. Elsner, Paris, France, and R. Gasch, Mainz, Germany. Eng. Pat. 8293, May 14, 1891. 6d.

See under VII., page 926.

An Improved Method or Process for the Production of Zinc or Spelter from Ores or Compounds containing the same. C. James, Swansea. Eng. Pat. 11,563, July 7, 1891. 6d.

THE ore, consisting chiefly of sulphide, is partially roasted or is mixed with roasted ore or with native carbonate or oxide in suitable proportions, and is then heated in a reverberatory furnace in a reducing atmosphere. The mixture of zinc vapour, sulphur dioxide, products of combustion, &c. is led into a separate and easily accessible condensing chamber or through tubes surrounded with water where the zinc is deposited.—H. K. T.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Production of Ozokerite in the United States. E. W. Parker. Eng. and Mining J. 1891, 127.

See under III., pages 910—912.

Researches in Electro-Chemistry. F. EXNER. Monatsb. Chem. 1891, 12, 276—303.

THE authors made experiments on the differences of potential produced at a contact of metals with various liquids. The method used was a modification of W. Thomson's dropping-electrode method, carried out as follows:—The dropping-electrode is connected with the electrometer, and from it mercury drops into the inside of a cylinder which is saturated with the liquid under investigation. The best material for such cylinders is hard gas-coke, and the small correction required to allow for production of electricity by friction is determined beforehand by a blank experiment, in which the mercury is allowed to drop into a clean cylinder connected to earth.

It is generally allowed that the differences of potential produced by the contact of a metal with a liquid, or of one liquid with another, are related in a definite way to the thermo-chemical value of the reaction which is thereby produced. But the exact nature of this relation has never been definitely ascertained, even in the cases which have already been investigated, viz., batteries in action and galvanic polarisation. There are many discrepancies between the observed values and those calculated from thermo-chemical data. The cause of these discrepancies has never been satisfactorily explained. W. Thomson first propounded the view that the electrical energy produced by any chemical reaction is exactly equivalent to

the thermo-chemical value of that reaction. More recently belief has gained ground that it can only represent a portion of this value, inasmuch as heat cannot be completely converted into electrical or mechanical energy. This portion is called by Braun the useful effect, and by Helmholtz, free energy. The author is inclined to return to Thomson's original theory and believes that the newer views have no real basis either in theory or experiment.

As far as experiment is concerned there are two things to be determined; the electrical energy, which is easily measured; and the thermo-chemical, which can only be measured when the chemical reactions which come into play are completely known. The latter is seldom the case, even with well-known batteries, like Bunsen's; and it is noticeable that the largest discrepancies occur in cases where the nature of the chemical reaction is doubtful. This is especially true in combinations which contain silver or lead as the negative pole, for here there are unknown quantities of peroxides formed, and the negative heat of combination of these cannot be allowed for in the calculation. Indeed, there are cases in which the electrical energy exceeds the thermo-chemical; and these would appear to offer insuperable difficulties to the advocates of the "useful effect" theory. All heats of reaction are really functions of temperature, and hence the electrical and thermal measurements should be made under similar circumstances; that this is not an unimportant matter is shown by the large temperature coefficients of many galvanic cells. It is also to be remarked that in all cases where the nature of the chemical reaction is thoroughly understood, there is agreement between theory and calculation; for example, in the elements investigated electrically as well as thermally by J. Thomson, in the combinations between bromine and iodine investigated by the author, and also in the measurements of galvanic polarisation. We ought also to consider that theory indicates the advisability of returning to Thomson's view, and regards the action of a cell as consisting in the (complete) transformation of electrical energy into heat, rather than as a (partial) transformation of chemical energy, primarily into heat, and secondly into electrical energy. The latter is the usual view, but the author's experiments do not support it. According to his theory of galvanic polarisation, the electro-motive force produced in any case depends upon the value of the heat of combination of the separated ions. This, however, must be a function of the temperature which would approach to zero at the temperature of dissociation of the substance; hence, also the electro-motive force of polarisation ought to diminish with temperature, and should become zero at this particular temperature. Poincaré has completely verified this in a recent research, in which he has shown that in the case of fused salts polarisation actually diminishes to zero when the temperature is raised to the dissociation point.

Improvements in and Apparatus for the Separation of Gold and Silver from Ores or Materials containing them. W. D. Bohm, Acton. *Eng. Pat.* 21,221, December 30, 1890. *Sd.*

A solution of common salt of sp. gr. 1.15 is prepared, to which is added $\frac{1}{2}$ to 20 per cent. of barium or calcium acetate, 1 to 10 per cent. of oxalic acid, and $\frac{1}{2}$ to 2 per cent. of potassium cyanide. The powdered ore, either roasted or not, is supported on a porous diaphragm placed in a vat, and the above solution is pumped through it until the gold and silver are extracted. The solution may be assisted by an electric current passing between a carbon anode placed beneath the diaphragm and a copper cathode placed in the liquid above the ore.

The dissolved gold and silver are separated by passing the liquid through shavings of an alloy of zinc with some electro-positive metal such as potassium or sodium (2½ per cent.). A trace of cadmium may also be added.—H. K. T.

Effect of Cooling on the Viscosity of Oils. Bender, Mitth. Konig. techn. Versuchs. Berlin, 1891, **9**, 100—135.

THE experiments, the results of which are detailed in this paper, were undertaken with a view to ascertaining what effect the cooling of mineral oils has on their viscosity at 20° C. Theoretically a considerable effect is conceivable, inasmuch as at lower temperatures a separation of paraffinic constituents may occur which may not be capable of satisfactory detection in dark-coloured oils when in a state of solution at higher temperatures, but may nevertheless affect the viscosity. The investigation was carried out as follows:—

A.—The determinations of viscosity at 20° C. were made after the oils had stood for several days at a temperature of —20° C., and then—

1. After standing for a day and careful warming to 20° C.
2. After heating to 50° C., and slowly cooling to 20° C.
3. After heating to 100° C., and slowly cooling to 20° C.

B.—For control purposes the experiments under A. were repeated with the corresponding samples after these had been once more cooled to —20° C.

The determinations were made in Engler's apparatus, and the oils examined consisted of mineral oils and mixtures of mineral oil with fat oils.

Tables are given which show that after cooling the degree of viscosity has increased, and this increase is more marked in the case of thick oils than in that of thin oils. Of the oils heated to 50° C. and 100° C., the thick ones showed a higher state of fluidity, whilst the condition of the thin oils was very little affected. After the second cooling the differences became even more marked.—T. L. H.

The Restoration of India-Rubber Articles that have become Brittle. Beibl. zu den Ann. d. Phys. u. Chem. 14, 514.

The articles are placed in a mixture of two parts of water and one part of ammonia. After from a few minutes to half an hour they will have recovered their former elasticity.

The Resin of Doona Zeylanica Thw. E. Valenta.
Monatsh Chem. 1891, 12, 98—106.

At the Colonial International Exhibition of 1887 there was exhibited a colourless resin, of which it was stated that its solution in turpentine or spirits makes an excellent and useful varnish. The author has proved that this resin is obtained from the *Doona Zeylanica Thw.*, a tree which grows to a very considerable height in the central province of Ceylon; it is closely related to, but not identical with, the gum known as doona, and also with the chai-resin obtained from *Shorea rubrifolia*.

Doona resin is generally yellowish and transparent, but sometimes translucent owing to the presence of small air bubbles and globules of a strongly refractive liquid; it has a slight pleasant smell, but no taste. Its specific gravity is 1.1362 at 17.5°, the error due to the presence of air bubbles being eliminated; when heated it softens and becomes sticky, then melts and turns brown, and finally takes fire and burns with a smoky flame, leaving 0.007 per cent. of ash, which consists principally of calcium carbonate, alkalis, and a small quantity of oxide of iron. It is completely soluble in toluene and xylene, and partially soluble in methyl alcohol, alcohol, amyl alcohol, oil of turpentine, and acetone, yielding lustrous varnishes of varying consistency; it dissolves in cold concentrated sulphuric acid, giving a granite-red solution which turns brown after some time.

By treating doona resin successively with various solvents it can be resolved into an acid α -resin, and two (β - and γ -) indifferent resins. The α -resin (about 65 per cent. of the original substance) can be obtained by digesting finely divided doona resin with 90 per cent. alcohol at 30°—35°, and evaporating the filtered solution; it is a brittle, yellow substance, melts at 115°, and gives on analysis numbers which agree well with those required by a compound of the composition $C_{24}H_{39}O_2$.

The β -resin (about 15 per cent. of the original substance) is obtained when the portion insoluble in 90 per cent. alcohol is extracted with ether, and the extract mixed with alcohol. It softens at 120°, melts at 150°—160°, and seems to have the composition $C_{21}H_{33}O$; it gives good varnishes with benzene, toluene, carbon bisulphide, &c.

The γ -resin (about 20 per cent. of the original substance) is a colourless, transparent substance, which seems to have the composition $C_{31}H_{49}O$; its solutions in toluene and xylene give, on evaporation, a very solid, colourless layer of varnish which is highly resistant towards acids and alkalis.—F. S. K.

Effects of High Temperatures on the Insulation Resistance and Inductive Capacity of Vulcanised India-Rubber. W. Mayer, jun. The Electrical Engineer, New York, 1891, 12, 159, and Abs. Proc. Inst. Civil Eng. 105, 1891, 89.

SOME of the underground street-ducts in the city of New York, owing to defective pipes of a steam company, are exposed to temperatures ranging as high as 200° F., and it was found that in such localities the lead-cased cables with impregnated fibrous dielectric rapidly fell in insulation. Experiments on the electrical qualities of india-rubber cores submerged in water raised to boiling point showed that this material was better adapted for such high temperatures. The observations obtained on three samples of core are plotted in a diagram, with the temperature and resistance as abscissa and ordinate, and show that at 212° F. the resistance was 12.4 megohms per statute mile, and one-eleventh of the value at 150° F., while the capacity at the former temperature was 2.4 times that of 100° F., the material returning also to its original values on re-cooling.

As in general only a small portion of a cable would be exposed to such excessive heat, the lowering therefrom of the total insulation of the circuit would be comparatively slight.

It is of interest to note that these cores have withstood such temperatures in actual use on high potential circuits for more than a year without deterioration.

PATENTS.

Improvements in the Method of and Apparatus for Rendering Textile Fabrics Waterproof by One Treatment or Process. J. Miller, sen., and J. Miller, jun., Manningham. Eng. Pat. 9711, June 23, 1890. 11d.

THIS invention relates to a machine for the continuous manufacture of waterproofed and stiffened textile fabrics, using ingredients soluble and insoluble in water. A series of tanks and rollers is so arranged that the cloth in passing from one kind of liquid to the other is freed from the former by nipping rollers and dried, if necessary, on heated cylinders.

The waterproofing ingredients soluble in water are preferably the acetates of aluminium, zinc and calcium along with albumen, mixed in certain proportions according to conditions. The insoluble ingredients are paraffin wax, Japanese wax, and beeswax.—H. S.

Improvements in Rendering Canvas and other Fabrics Rot-proof. J. Williams, London. Eng. Pat. 12,513, August 11, 1890. 4d.

THE fabric is first soaked in any suitable salt of copper and then passed through a solution of any "convenient sulphocyanide, such as sulphocyanide of ammonium and sulphurous acid, or a bisulphite." Other reducing agents may also be employed. After sufficient treatment the fabric is passed through a tank of running waters and dried. By this means the fabric is coated or "its surface impregnated with subsulpho-cyanide of copper," and thereby rendered rot-proof.—H. S.

Improvements in Colours or Pigments for Making Imitation Metallic and Coloured Enamels, Paints, and Printing Inks. W. Davison, London. Eng. Pat. 15,743, October 4, 1890. 4d.

THE inventor uses "oils, pitch, picric acid, nitrobenzole, aniline, luteicene resin, gums, shellacks, varnish, spirits, naphtha, and other eosine aniline products, by-product of soaps, tar, ammonia, and turpentine" mixed in suitable proportions for the desired purpose.—E. G. C.

Improvements in the Preparation of Colours for Dis-tempering. J. Hauke, Dresden, Germany. Eng. Pat. 17,316, October 30, 1890. 4d.

THE inventor prepares a "binding material" by boiling with water 2 parts of rye-busks and one of potato starch. One part of this size is required for about 3 parts of pigment. The size has the following advantages: it does not gelatinise or thicken in cold weather; when applied to walls it is unaffected by damp air; it is not liable to decompose; the colours mixed with it may be dried and sold in that condition, merely requiring mixture with water to render them fit for use.—E. B.

Improved Waterproof Paper. A. A. Haigh, Manchester. Eng. Pat. 18,838, November 21, 1890. 4d.

THIS inventor employs resin and a substance possessing the trade name "almédina" (known also as "potato-rubber"), dissolved in naphtha; and colouring matters may be added. Various methods of applying it to the paper may be adopted, but "spreading" is preferred.—E. G. C.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

The Treatment of Leather for Dyeing and Colouring Purposes. E. M. Shaw, J. Soc. Dyers and Colourists, November 1, 1891.

PATENTS.

Improved Process and Apparatus for Tanning Hides and Skins. L. A. Groth, London. Eng. Pat. 18,385, November 14, 1890. 8d.

THIS invention relates to improvements in the process and apparatus for tanning hides with or without the aid of electricity, in which agitation of the tan-liquor and hides is employed. In apparatus of the kind referred to, it often happens that the whole mass of tan-liquor is carried round in the tan-pit or vat with the hides so that both the liquor and hides rotate together in the same direction, the practical effect being much the same as if both were stationary in the pit or vat, the desired effect being thus more or less hindered. To effect the agitation of the tan-liquor independently of the motion of the hides, the inventor employs paddles or stirrers, or causes the liquor to circulate by means of a pump which draws the liquor from the lower part of the pit and returns it to the upper, or similar device. For drawings and particulars of the apparatus employed, the specification must be consulted.—B. H.

An Improvement in or relating to the Manufacture or Treatment of Size, the same being also applicable to the Manufacture or Treatment of Glue or of Gelatin. B. Cannon and W. J. Cannon, Lincoln. Eng. Pat. 10,596, June 22, 1891. 4d.

THE object of this invention is to obtain a product free from the disagreeable odour inherent to such substance as at present produced, and pervaded with an aromatic or aromatic and antiseptic odour. To effect this, the material from which the size, glue, or gelatin is prepared, or the size, glue, or gelatin itself is incorporated with a suitable proportion of "nitro-benzene" or "other suitable deodorising, aromatic, or antiseptic substances, such as benzoïn, camphor, myrrh, olibanum, and other gums; eucalyptus, lavender, mint, rosemary, bergamot, cedar, cloves, pepper-mint, rose, lemon, and other essential oils; or musk, castor, civet, ambergris and other animal perfumes." The quantity of any such substance required depends on the result required. As an example, one part of musk would suffice for about 7,000 parts of size.—B. H.

Memoranda of the Origin, Plan, and Results of the Field and other Experiments conducted on the Farm and in the Laboratory of Sir J. B. Lawes, at Rothamsted. June 1891.

*Experiments on Permanent Meadow Land. Thirty-sixth Season (area under experiment about 7 acres).—*The land is an old meadow, and no seed has been artificially sown within the last 50 years, perhaps not since grass was first laid down. The manuring has been, with some exceptions, the same for each plot year after year, since the commencement of the experiments. For the first 19 years only the first crop was mown, the second crop being generally fed off by sheep. The highest average yield over the 14 years, 1876—1889, taking both crops, was over 86 cwt. per acre, and this was obtained with an application of potassium sulphate (500 lb.), sodium sulphate (100 lb.), magnesium sulphate (100 lb.), superphosphate (3½ cwt.), sodium silicate (400 lb.), and ammonium salts (600 lb. per acre). The plot which had the same mineral manure (without the silicate), and sodium nitrate (550 lb.) instead of the ammonium salts, yielded 65 cwt. per acre or 2 cwt. more than the plot with the same minerals and 400 lb. of ammonium salts. The average results with ammonium salts alone (400 lb.), and with sodium nitrate alone (275 lb.), were respectively 29 cwt. and 40 cwt. per acre. With regard to the plots receiving mineral but no nitrogenous manure, the highest average yield (45 cwt.) was obtained with the complete mineral manure; another plot which had all the minerals gave 41 cwt., whilst the omission of potash brought the yield down to 30 cwt., which is not much higher than that of the unmanured plots (26 and 29 cwt.). With regard to the amounts obtained in 1890, the yield was generally lower than the average over the preceding 14 years.

*Experiments with Barley. Fortieth Season (area under experiment about 4·25 acres).—*The continuously unmanured plot gave an average amount (for the 38 years) of nearly 17 bushels of dressed grain per acre, and 13 bushels in 1890. Where there was an application of mixed mineral manure (without nitrogen) the average yield was 22·5 bushels and the yield in 1890 nearly 18 bushels. Dividing the mixed minerals into superphosphate on the one hand, and potassium, sodium, and magnesium sulphates on the other, far more effect is produced by the application of superphosphate alone than by the other minerals; in fact, the average yield of grain and the yield in 1890, in the plot which had superphosphate alone, were nearly equal (21·75 and 16·75 bushels) to the plot treated with the complete mineral manure. The same relative effect is shown where the respective minerals are given in conjunction with nitrogenous manure. The average yields with ammonium salts alone (200 lb.) and sodium nitrate alone (275 lb.) were 29·25 and 32·75 bushels, the produce in 1890 for the two plots being 20·5 and 29·5 bushels. The greatest yield, 53 bushels per acre, was obtained where 14 tons of farmyard manure is applied yearly (the average yield was 48·6 bushels). The next highest yield (average 46·25; 1890, 46·6 bushels), was from the plot which had the mixed minerals (with sodium silicate) and sodium nitrate (275 lb.); but nearly the same amount was obtained on the plot which had superphosphate (and silicate) and sodium nitrate alone.

*Experiments with Wheat. Forty-eighth Season (area under experiment about 11 acres).—*The average yield per acre of dressed grain during the 38 years previous to 1890, on the unmanured plot was 13 bushels, and the yield in 1890, 19·4 bushels. The plot which had farmyard manure (14 tons) gave an average yield of 34 bushels, and in 1890

50 bushels per acre. The next highest average yield, 36·5 bushels, was obtained from the plot manured with potassium sulphate (200 lb.), sodium and magnesium sulphates (each 100 lb.), superphosphate (3·5 cwt.), and ammonium salts (600 lb. per acre). The plot which received the same minerals and 400 lb. of ammonia gave an average yield of 32·8 bushels, and in 1890, 44·3 bushels; whilst the plot manured like the last, but on which the ammonia salts were sown in the autumn instead of in the spring, gave an average yield of 30·5 bushels, and 48 bushels in 1890. The mixed minerals alone (without nitrogen) gave an average yield of 15 bushels, and in 1890, 19·3 bushels, nearly exactly the same as the yield of the unmanured plot. The high yields in 1890 were partly due to the season and partly to the fact that the half of the field from which the results were obtained was thin sown and therefore partially fallow the year before, in order to clean the land.

Experiments on Mangel-Wurzel. Sixteenth Season (area under experiment, about 8 acres).—The highest yield of roots (36 tons 4 cwt.) was obtained on the plot which received farmyard manure (14 tons), superphosphate (3·5 cwt.), and a cross dressing of rape cake (2,000 lb.). The plot which had the same manures with the addition of ammonium salts (400 lb.) gave only 30 tons 13 cwt. Of the plots which had no dung or rape cake the highest amount of produce (27 tons 1 cwt. of roots) was yielded by the plot manured with superphosphate (3·5 cwt.), potassium sulphate (500 lb.), sodium chloride (200 lb.), magnesium sulphate (200 lb.), with a cross dressing of sodium nitrate (550 lb.). Where no nitrogen but only minerals were given the yield varied from 5 tons 13 cwt. to 7 tons 1 cwt.; the yield on the unmanured plot was 6 tons 5 cwt. The importance of potash is shown by the fact that when superphosphate was applied with a cross dressing of nitrogenous mineral or organic manure (except sodium nitrate), the yield varied from over 10 tons to over 17·5 tons; whilst superphosphate and potassium sulphate with the same cross dressings gave yields varying, according to the cross dressing, from over 19·5 tons to nearly 31 tons. The plots which had superphosphate alone, and superphosphate and potassium sulphate, and were cross-dressed with sodium nitrate, gave very similar results, the yields of roots being respectively 21 tons 18 cwt. and 21 tons 12 cwt. The average results for these plots were also very close. The produce in 1890 was on every plot greater and generally much greater than the average produce of 1890 and the four preceding years.

Experiments on Potatoes. Sixteenth Season (area under experiment 2 acres).—In 1890 the produce was on each of the plots higher than the average of the five years 1886–90. The greatest weight of tubers was obtained from the two plots which received, since 1883, 14 tons of farmyard manure, the yield being 6 tons 15½ cwt. and 6 tons 17 cwt. The next highest yields were obtained on the plots which had mixed minerals (this Journal, 1890, 871) together with ammonium salts (400 lb.) or sodium nitrate (550 lb.), the yield on these two plots being 6 tons 7·75 cwt. and 6 tons 3·75 cwt. respectively. With the same amounts of ammonia or nitrate, but without the minerals, the produce was only about 2 tons and 2·5 tons, whilst with superphosphate alone, and with mixed minerals alone, the yields were respectively 2 tons 12·5 cwt. and 3 tons 3 cwt.

The following papers have been published since June 1890 (compare this Journal, 1890, 871):—

Series I.—Reports of Field Experiments, &c.

42. On Nitrification. Part IV. (Chem. Soc. J. 1891).

84. Results of Experiments at Rothamsted on the Question of the Fixation of Free Nitrogen. (Agric. Students Gazette, N.S. 5, 1890–91.)

85. Observations on Rainfall, Percolation, and Evaporation, at Rothamsted; with tabular results for 20 harvest years (September 1 to August 31), 1870–1 to 1889–90, inclusive. (Proc. Inst. Civil Eng. 105, 1891).—N. H. J. M.

Comparative Influences of Ferrous and Calcium Sulphates on Nitrification and on the Conservation of Nitrogen. P. Pichard. Compt. Rend. 1891, 112, 1455–1458.

EXPERIMENTS were made with soils composed of (1) pure sand; (2), sand and $\frac{1}{100}$ part of clay; (3), sand and calcium carbonate; and (4), sand, clay, and calcium carbonate, these soils being mixed with organic nitrogen (cotton oil-cake) at the rate of 1 grm. per kilo. and kept of a proper degree of humidity during the progress of the experiments.

With the addition of $\frac{1}{1000}$ part of ferrous sulphate, the production of nitric nitrogen during a period of seven months, was increased in the case of soil (1) from 1·43 (without such addition) to 10·40 per cent. of the nitrogen added, and in that of (2) from 5·10 to 15·92 per cent., but was reduced in the case of (3) from 5·10 to 2·55, and in that of (4) from 7·14 to 6·43 per cent. The addition of $\frac{1}{2000}$ part of calcium sulphate, under the same conditions, increased the formation of nitric nitrogen to the extents of 11·43 (1), 13·67 (2), 23·67 (3), and 34·48 (4) per cent.

As regards the prevention of loss of nitrogen, ferrous sulphate was found highly efficacious with soil (1), less so with (4), and indifferent with (2) and (3). Compared in this respect with ferrous sulphate, calcium sulphate was superior in its action with soils (2) and (4), little different with (3), and inferior with (1).

From the results obtained it would seem that, as a manure, ferrous sulphate is beneficial with soils which contain an excess of silica and are deficient in humidity, clay, calcium carbonate, and iron oxide, but with other soils, the addition of calcium sulphate is more advantageous.

Ferrous sulphate is useless, if not indeed injurious, as an addition to ferruginous soils. It may, however, be employed with advantage for fixing the ammonia of manures in which the formation of that substance takes place rapidly, but its antiseptic properties unfit it for admixture with manures which decompose slowly.

Chlorosis, when due to defective nutrition and not to meteorological or cryptogamic influences, is combated quite as well by calcium sulphate as by ferrous sulphate.—E. B.

PATENT.

The Manufacture of Artificial Manure or Manures from the Dross or Refuse of Esparto and other Grasses, Straw, Rags, Wood, and other Materials used in the Manufacture of Paper. E. Pearman, Hemel Hempstead. Eng. Pat. 14,587, September 16, 1890. 4d.

This invention consists in mixing together the dross or refuse of esparto, straw, and other materials used in paper-making, with sand, charcoal, soda, nitric acid, sulphuric acid, spirits of salts, ammonia, and several other salts "in such or any proportions as may be required."—E. J. B.

XVI.—SUGAR, STARCH, GUM, Etc.

Xylose from Maize Cobs. W. E. Stone and D. Lotz. Ber. 1891, 24, 1657–1658.

XYLOSE can be obtained by extracting maize cobs with boiling 2 per cent. soda, precipitating the gum from the alkaline solution by the addition of alcohol, and then hydrolysing it with 2 per cent. sulphuric acid. The yield is small.

—F. S. K.

A New Isomeride of Mucic Acid and the so-called Paramucic Acid. E. Fischer. Ber. 1891. 24, 2136—2143.

Heating with quinoline or pyridine at 140—150° converts mono- and di-basic acids of the sugar group into optical isomerides, which differ from the original acid in having the carboxyl attached to the neighbouring asymmetric carbon atom. Under similar treatment mucic acid yields a new isomeride, to which the name *allomucic acid* has been given; but owing to the insolubility of mucic acid in quinoline, aqueous solutions and closed vessels have to be used, and pyridine is found to be the more convenient base, the chief function of the base is to prevent the formation of lactone, which would interfere with the desired transformation.

The results obtained dispel the opinion hitherto entertained that mucic acid is characterised by yielding no lactone, and moreover provide a valuable step towards the synthesis of members of the dulcetic group.—D. A. L.

PATENTS.

Improvements in the Production of Invert Sugar. A. Wöhl and A. Kollrepp, Berlin, Germany. Eng. Pat. 17,557, November 1, 1890. 6d.

The invention relates to the production of a pure tasting invert sugar from inferior raw sugars; the process is a modification of that previously described in Eng. Pat. 16,540 of 1889 (this Journal, 1890, 878).

The sugar solution is made of a concentration of about 85° B, and is inverted with very dilute acid at 110° C. To determine the amount of acid necessary, a portion of the raw sugar is ignited, and the amount of acid which is necessary to neutralise the alkali in the residue is sufficient to invert the sugar. During the progress of the inversion air or steam are blown through the solution; this treatment expels the greater portion of the volatile acids. The inversion is completed in about one hour, and very little colour is produced.—A. L. S.

Improvements in Apparatus for Washing Sugar. R. F. Cordero, Rubio, Venezuela. Eng. Pat. 12,808, July 28, 1891. 8d.

The sugar to be washed is placed in a conical-shaped vessel, and "alcohol of about 38°" poured over it. The alcohol which issues from the bottom of the cone is received in a closed receiver, and the process of washing continued until the alcohol passing into the receiver is colourless; the supply of alcohol is then stopped, and air pumped through the sugar until all alcohol is removed from the sugar; the air is washed to remove the alcohol. The alcohol containing the molasses is distilled in special apparatus, which yields a spirit of the original strength, and the molasses remain behind in the boiler.—A. L. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

PATENTS.

Improvements in and relating to the Manufacture of Yeast. H. H. Lake, London. From A. Brunn, Rodstrup, Denmark. Eng. Pat. 15,352, September 27, 1890. 6d.

The sweet wort is prepared from 75 per cent. of barley, rye or maize, which has been washed, malted, and ground; 5 per cent. of barley, and 20 per cent. of rye or maize; the latter are soaked previous to grinding. The grain thus divided is soaked in water for 24 hours, a little muriatic acid being added. It is then mashed in the usual way, and the wort

filtered through animal charcoal or other substances, whereby an almost colourless fluid of 10 per cent. by the saccharometer is obtained.

The wort is fermented at a constant temperature of 30° C., and with frequent aeration. The fermentation is concluded in 10 hours, and the yeast is then separated either by precipitation or centrifugal separation.—A. L. S.

Improvements in Brewing Beer. J. Cox, Greenwich. Eng. Pat. 18,708, November 19, 1890. 4d.

A SACHARINE decoction of hops is fermented with a solution of raisins, currants, or sultanas which has stood at 25—40° C. until fermentation has set in.—A. L. S.

Improvements in Pneumatic Malting Drums. J. Y. Johnson, London. From "Berliner Actiengesellschaft für Eisengiesserei und Maschinen-Fabrikation, vorm. T. C. Freund and Co.," Charlottenburg, Germany. Eng. Pat. 3666, February 28, 1891. 8d.

A NUMBER of perforated metal tubes are contained in the drum, by means of which air of suitable temperature and moisture may be passed through the grain to be malted.

By an arrangement which is particularly described in the specification, as the drum is rotated the air is always introduced by the lowest of the tubes, and passing through the body of the grain is withdrawn by the uppermost of the tubes.—A. L. S.

Process for the Preparation of Wort from Malt, alone or Mixed with Unmalted Cereals. C. Rach, Chicago, U.S.A. Eng. Pat. 12,506, July 23, 1891. 4d.

When using malt alone, the ground malt is mashed at about 145° F., and allowed to stand 15—20 minutes. The clear supernatant solution is then drawn off, and the thick mash remaining heated in a steam cooler to 246°—268° F. for 45 minutes. This is then cooled and mixed with the clear solution previously drawn off so as to produce a final temperature of 165° F. After 30—40 minutes the taps are set in the usual way.

If unmalted cereals are also used, they are mixed with about one-sixth their weight of crushed malt and mashed at 122° F. The temperature is then gradually raised to 268—291° F., and, after standing 45 minutes at this temperature, the raw cereal mash is mixed with the malt mash prepared as above; the temperature of the final mash is to be about 165°, and after standing 30 to 40 minutes, the wort is drawn off as usual.—A. L. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A).—CHEMISTRY OF FOODS.

On Roasting, Malting, and Drying Processes, with special reference to Cocoa. A. Stutzer. Zeits. f. angew. Chem. 1891, 368—375.

This paper deals with the changes effected by roasting and drying processes as applied to food-substances, with especial reference to cocoa.

The author is of the opinion that more care should be exercised in the roasting of cocoa than has hitherto been the case, and considers that if this operation be properly performed, the use of alkalis to "open up" the material, or the addition of essences, is unnecessary. A roasting apparatus is described, in which the heat can be very carefully regulated and evenly applied.

Analyses are given of a sample of cocoa prepared by roasting alone and of ordinary commercial samples. The following are the methods of analysis:—

Fat.—In the manufacture of cocoa this substance is reduced by hydraulic pressure to 25–30 per cent. The temperature should be kept as low as is practically feasible during this operation, and the material should be protected from the air. The percentage of fat is determined in the usual way by extraction with anhydrous ether.

Nitrogenous Matters.—The nitrogenous constituents of cocoa are ammonia, theobromine, amides, digestible albumen, and indigestible substances. The author has already shown (Report, 1882, 169) that a very small proportion (about 42 per cent.) of the nitrogenous constituents of cocoa are digestible. The nitrogenous constituents of cocoa fall into three groups. The first, non-proteids (ammonia, theobromine, and amides), are soluble in water in the presence of cupric hydrate. The second, digestible albumens, are insoluble in this solvent, but dissolve in acid gastric juice or alkaline pancreatic juice. The third, consisting of undigestible constituents, are insoluble in these reagents. The total nitrogen is first determined in 1 gm. of the cocoa powder by Kjeldahl's method. Two grms. are then mixed with freshly precipitated cupric hydrate, washed with water, the filtrate distilled with magnesia, and the ammonia titrated. The ammonia should not exceed 0.1 per cent. A greater amount shows that this substance has been added during the manufacture. Addition of ammonia, as also of potassium and sodium hydrates, has the effect of making the ash of cocoa less soluble.

Theobromine ($C_7H_5N_4O_2$) is an important constituent of cocoas. Raw cocoa beans contain on an average 1.5, crude cocoa 1.6, cocoa-powder 1.8–2.0 per cent. of theobromine. Together with this is 0.15 to 0.20 per cent. of theine. Theobromine is best determined by the method of Weigmann, in which 20 grms. of cocoa are boiled out with water, the albumen precipitated with ferric acetate, and the filtered liquid mixed with phospho-tungstic acid. The nitrogen in the resulting precipitate is then determined.

The nitrogen due to amides is found by deducting the theobromine- and ammonia-nitrogen from the total non-protein nitrogen. The following factors are used:—

Ammonium (NH_4)	1.28
Theobromine ($C_7H_5N_4O_2$)	3.15
Amides	6.25

The factor for amides is that usually used for proteids.

The determination of the digestible albumen was effected by treating the cocoa powder first with acid pepsin solution and afterwards with alkaline pancreatic fluid. The insoluble residue was washed with water and its nitrogen determined. This, deducted from the total albuminous nitrogen and multiplied by 6.25, gives the digestible albumen. In order to render the determination more exact, the cocoa powder should be first freed from fat, since the author has previously shown that the latter offers a mechanical resistance to the action of the digestive fluids.

In order to determine the effect of heat upon the digestibility of the albumen of cocoa, samples of Ariba, Bahia, and Machala cocoa beans were powdered, the fat extracted with ether, and the residue again powdered and the digestible albumen determined. The extracted samples were then roasted and the digestible nitrogen again determined.

In 100 parts of total nitrogen the following quantities were undigestible:—

	Raw.	Roasted.
Ariba beans	23.2	39.7
Machala beans	22.8	40.3
Bahia beans	19.3	40.3

Experiments were made on the rate at which the cocoa powder dissolved in acid pepsin solution, but without

noteworthy result. The analysis of cocoa also involves the determination of starch and sugar, of woody fibre (in the samples examined the latter varied from 3.36 to 5.75), and of the amount of organic matter soluble in cold water and of the nitrogen which it contains.

The analysis and properties of the ash of cocoa also give important information as to the treatment which the cocoa has undergone in the course of manufacture. Dutch cocoa usually contains potash or soda, whilst the German varieties frequently contain ammonia. The effect of these reagents is to render the ash, especially the phosphates, less soluble.

The following conclusions were arrived at:—

The present methods of roasting are unsuitable, the duration of the operation is too long, the temperature variable, and provision is not made for the escape of evil-smelling, combustible vapours. The use of potash, soda, and ammonia, to "open up" (*ausschliessen*) the cocoa is unnecessary if the roasting is properly conducted. The presence of these reagents can be detected by analysis. The use of essences and perfumes is injurious and only necessary to disguise defective roasting. The percentage of theobromine in different varieties of cocoa bean is practically constant and is not greatly influenced by the method of preparation. The value of cocoa as a food-substance depends upon the amount of digestible albumen. The ratio of this to indigestible nitrogenous matter is usually 4:3, but with too high a temperature during the roasting it may become 4:4 or 4:5. The percentage of cocoa-butter should not exceed 30 per cent.—H. K. T.

The Proteids or Albuminoids of the Oat Kernel. T. B. Osborne. Amer. Chem. Jour. 1891, **13**, 327–347 and 385–413.

The author draws the following conclusions from the results of his researches on the proteids of the oat kernel:—

The proteid removed from freshly-ground oats by extraction with dilute alcohol (Norton's *glutin*), when dehydrated by absolute alcohol and dried over sulphuric acid, is a light yellowish powder, insoluble in pure water, as well as in absolute alcohol, although soluble in mixtures of alcohol and water; it dissolves also in dilute acids and alkalis, and from these solutions it is precipitated by *exact* neutralisation. From its solution in 60 per cent. alcohol it is obtained as a yellowish slimy mass by evaporating off the alcohol. It is remarkable for the large amount of sulphur which it contains. Its composition is given in analysis No. I. If heated for some time with dilute alcohol, it coagulates and is no longer soluble in that liquid, although its composition remains apparently unchanged. The analysis of this coagulated modification is numbered II.

If, instead of extracting the oats directly with dilute alcohol, they are first treated with water, or 10 per cent. sodium chloride solution, the proteid soluble in alcohol undergoes change and the resulting substance has different properties. It is much more soluble in dilute alcohol than proteid No. I. and is not coagulable. If wet with absolute alcohol the moisture absorbed from the atmosphere renders it gummy and tenaciously adhesive, unlike No. I. Its analysis is numbered III.

The principal proteid extracted by 10 per cent. alcohol behaves towards reagents like the myosin-globulin of animal muscle, first noticed by Weyl. The author finds its coagulation temperature to be much higher (80°–100°), however. This proteid appears to be the result of a transformation similar to that by which myosin is formed from myosinogen. The largest amount of this proteid obtained amounted to 1.3 per 100 parts of oats. Its analysis is numbered IV.

The proteid extracted, after complete exhaustion of the oats with dilute alcohol of 0.9 sp. gr., by 10 per cent. sodium chloride solution, and that obtained by extraction with dilute potash ($\frac{2}{10}$ per cent.), also after exhaustion with alcohol, are regarded by the author as identical with that obtained by extraction with sodium chloride directly. These are numbered V. and Va.

If the ground oats are extracted with $\frac{2}{10}$ per cent. potash without previous treatment with alcohol, nearly the whole of the proteid bodies are removed, and if, after precipitating

these, they are exhausted by alcohol in order to remove the proteid soluble in that liquid, the reozoining substance is regarded by the author as probably Johnson and Norton's *arenine*, which they obtained by extracting with dilute ammonia. Its analysis is numbered VI.

If, instead of extracting the oats directly with potash, they are first digested in water, the amount of proteid soluble in potash is much smaller, one hour's treatment with water rendering one-half, 24 hours' treatment, two-thirds, insoluble. What is then dissolved out by potash is the same as No. IV. Its analysis is numbered VII.

When ground oats are extracted with 10 per cent. sodium chloride solution, at 65°, a proteid separates, on cooling the extract, in the form of spheroids. It differs from all other proteids which have been described as yet. It is soluble in pure water, precipitated by the addition of a little sodium chloride, again dissolved by the further addition of sodium chloride, and finally precipitated completely by saturating the solution with salt. In the presence of a little sodium chloride and acetic acid it is soluble in alcohol of 0.9 sp. gr. It has been obtained crystallised in regular octahedra from its solutions both in water, as also in sodium chloride brine. The analysis of the spheroids is numbered VIII.

Water alone appears to dissolve very little protein substance, as Norton and Kreisler found, the three bodies so dissolved being (1) an acid albumen, (2) a globulin or globulins, (3) a proteose.

The Purification of Water by Metallic Iron. E. Devonshire. A Lecture before the Society of Arts, Mass. Inst. Techn., December 11, 1890. Techn. Quarterly, 1891, 4, 113—121.

Attention to the action of the ordinary sand filter for purifying water is purely mechanical, yet on account of the formation of what Pflücke terms bacteria-jelly, which is a sort of film formed on the surface after several days' working, it is capable of removing a considerable proportion of the bacteria present in the water before filtration. Sand filters do not, however, remove dissolved organic matter, nor the colour due to finely-divided clay or peat frequently met with in river or surface waters, even when the rate of filtration is as low as 30 galls. per square foot per day.

The necessity of removing the colour from the new water supply at Antwerp derived from the River Nethe caused the adoption of the process of filtration through the material known as Bischof's spongy iron. This method was efficient, but objectionable on account of its cost, and the rusting and clogging of the filter-beds which gradually took place. The difficulty was overcome by Anderson, the consulting engineer of the water company, who devised an apparatus consisting of a cylinder carried on hollow trunnions, one at each end, and capable of being revolved about its longer axis by spur gearing. A series of short curved shelves are arranged in steps at equal distances round its internal circumference; the sixth row of curved shelves being replaced by a set of small square plates set at an angle with the axis of the cylinder. Iron scrap (turnings, borings, &c.) is placed in the cylinder and is scooped up by the shelves and showered down through the water, which is introduced through the trunnion at one end where it is distributed by a baffle plate and finds its way out through the other, the mouth of which is bell-shaped and points vertically downwards so as to prevent the accidental exit of the finer particles of iron. The function of the small square plates is to direct the iron back towards the inlet end of the apparatus, and thus counteract the tendency of the current of water to carry the purifying material forward. By this means ample contact of the water with the iron is secured, while no rusting together is possible and the surfaces of the metal are kept continually clean by mutual attrition. The water, charged with a ferrous salt, comes in contact with the air on leaving the cylinder, ferrie hydrate is formed and entangles the suspended matter and oxidises the organic impurities. Micro-organisms are also removed either mechanically or by the direct toxic effect of salts of iron; the entire absence of free ammonia from the filtered water is characteristic of the iron process. Weekly analyses of the Antwerp water before and after filtration show that in actual practice on a large scale, the albuminoid ammonia is reduced to one-third of its original amount; free ammonia and nitrites entirely disappear, and nitrates are brought down to the smallest trace; the micro-organisms are reduced in number from 50,000—100,000 colonies per cc. to four or five, the highest number recorded being 20; the water is therefore practically sterilised.

The method has an important advantage over the high-pressure system, in conjunction with which alum has been generally used as a precipitant, inasmuch as the clogging of the filter throughout its depth that occurs with the latter, necessitating frequent washing by a reverse current, is avoided; the cost of the scrap iron is also less than that of the alum.

The actual cost of the process varies with the water to be treated, a water containing such organic matter or very finely-divided suspended matter, clogging the filters sooner than one containing an even comparatively large quantity of less finely-divided clay or mud. Thus the Antwerp water contains much organic matter both vegetable and animal, but little mud; before the introduction of settling reservoirs, the filters had to be scraped once a fortnight. At Dordrecht, on the other hand, where a water holding much fine clay in suspension but organically purer is treated, the filters run for five weeks.

The cost of the treatment at Antwerp for 1889 was 257 dol. for 234 million gallons pumped during the year,—a fraction over 1 dol. per million gallons, although the plant was working at half its capacity, a condition unfavourable to economy.—R. B.

Use of Galvanised Iron Pipes for Conveying Water.

R. Haines. Proc. Chemical Section, Franklin Inst., Jan. —Dec. 1890, 69—77.

From analyses of samples of water taken from artesian wells lined with tubes of galvanised iron, the author finds that where nitrates are present in any considerable quantity in the water ammonia in quantity is obtained; in consequence a good deal of zinc is taken into solution, the nitrates disappearing to a great extent. That zinc has a cumulative action on the system seems tolerably certain, but it is also certain that its action is far from being so injurious as the

action of lead. In very small quantities the zinc is practically harmless, but he considers that if the water to be transported contains any amount of ammonium salts, chloride of sodium and nitrates, as well as very small amounts of free mineral acids, &c. then zinc-coated pipes should most certainly not be used, but only pipes coated with a non-metallic interior surface.—T. L. B.

Local Standards in Water Analysis. R. Haines.

J. Franklin Inst. 1891, 131, 378—385.

ONE of the difficulties in the examination of drinking waters is the obtaining of a suitable standard with which to compare the results of analysis of any given water in order to form a correct judgment of its fitness for drinking purposes. A general standard is often misleading. Special local standards for each district are advised, and these may be obtained by collecting a considerable number of analyses of such well and spring waters as are in a natural uncontaminated condition; from these an average may be struck to form a standard of purity for the district in question. Such a "standard" cannot, however, be applied as a hard and fast rule to all waters in the locality, and for different classes of water different standards are necessary. Thus, river waters cannot be compared with well waters and so on. The author gives a number of results of analyses of well waters in the neighbourhood of Philadelphia, on the Pennsylvania side of the Delaware River.—T. L. B.

(C.)—DISINFECTANTS.

The Treatment of Phylloxera with Carbon Bisulphide and Vaseline. L'engrais and Chem. Trade J. November 7, 1891, 283—284. (Compare this Journal, 1891, 842 and 846—847.)

BISULPHIDE of carbon has proved, during recent years, to be the most certain insecticide, and its use has led to the preservation of a great part of the French vineyards.

Practice has made it apparent that bisulphide of carbon does not give quite such satisfactory results in very siliceous earth. Not easy to diffuse in some soils, and evaporating too rapidly in others, the sulphide does not so certainly produce its effect. Hence, has arisen the current opinion, that bisulphide of carbon suits certain soils and not others.

Since 1887, Dr. Albin Mennier has been endeavouring to render this action uniform, by assisting the diffusion of the carbon bisulphide in heavy soils, and preventing its evaporation in such as are too light, and finally by avoiding the injurious effect on the vine, produced by a considerable amount of evaporation in soil, heated by the summer sun.

The experiment was made of mixing bisulphide of carbon with petroleum oils, boiling at 300°—350° (vaselin), and of density 0.850—0.910, which are quite without injurious effect on the plants, even when present in large quantity. Numerous direct experiments have been made with these hydrocarbons on vines.

These high-boiling substances have the property of diminishing the evaporation of the bisulphide of carbon. Bisulphide of carbon, for example, can only be separated from ordinary alcohol by fractional distillation with great difficulty (Bertbelot). Methyl alcohol and acetone, benzene and toluene are further examples which may be selected from many others.

Although carbon bisulphide can be separated from vaselin by fractional distillation, on account of the great difference in boiling point, yet the evaporation of the former, at all events, at the ordinary temperature, is considerably diminished by the addition of vaselin, which retains considerable quantities for days, in spite of a considerable surface of evaporation.

In very light sandy soils the use of vaselin should, *a priori*, be favourable. On the other hand, vaselin which physically resembles the fats, readily penetrates into clay, and its use should therefore be also found advantageous in heavy land (clay and clayey sand).

Five thousand seven hundred kilos. of carbon bisulphide mixed with an equal weight or half its weight, of vaselin were employed in the department of the Rhône at various places, Vaugeray, Saint-Etienne-la-Varenne, Villié-Naorgon, &c.

In 1888, 2,500 kilos. were supplied to various proprietors in the Rhône district, who obtained such results that in 1889, 89,585 kilos., and in 1890, 242,392 kilos. were employed by a large number of vine-growers in the following departments:—Rhône, Isère, Ain, Saône et Loire, Côte-d'Or, Loire, Ardèche, and Drome.

From the indications given in the spring of the present year, the total amount of the mixture to be employed during 1891 may be estimated at 500,000 kilos.

The vaselin mixture is applied in the same manner as the pure sulphide. In practice it is found that the efficacy of the remedy is increased by inserting one portion at a distance, 10 or 12 cm. from the foot of the vine stock, and spreading the rest over the area of a hectare. Actually about 2,000—2,500 hectares of vineyard are under treatment in this way.

The increasing use of this remedy is obviously caused by its success in restoring diseased vines, and by the impression thus made upon the minds of the owners.

For four years this mixture has been employed over 15—20 hectares, situated at Saint-Etienne-la-Varenne (Rhône). This property was kept at the average rate of production by pure bisulphide, but its production has been increased three-fold by the new treatment. Phylloxera is no longer found on the roots, the vegetation is luxuriant, and numerous rootlets, a sure sign of increased vitality, have appeared.

The manure has not been altered for 10 years, so that the marked improvement can only be ascribed to the use of a more rational insecticide.

These results reflect the opinion of M. Balbiani, stated in his memoirs on phylloxera (1876):—

"The germ or embryo is much less certainly attacked by large doses of a poisonous vapour acting for a short space of time, than by even very small quantities, the action of which is slow but continuous."

Bisulphide of carbon mixed with vaselin theoretically fulfils this requirement.

XIX.—PAPER, PASTEBOARD, Etc.

The Colouring of Paper with Coal-Tar Dyes.
Papier Zeit. 1891, 16, 2182—2183.

See under VI., page 921.

PATENTS.

The Manufacture of Artificial Manure or Manures from the Dross or Refuse of Esparto and other Grasses, Straw, Rags, Wood, and other Materials used in the Manufacture of Paper. E. Pearman, Hemel Hempstead. Eng. Pat. 14,587, September 16, 1890. 4d.

See under XV., page 939.

Improvements in the Manufacture of Paper, Boards, and such like Materials. C. Weygang, London. Eng. Pat. 14,753, September 18, 1890. 6d.

THE inventor claims certain improvements on his former patents, Eng. Pats. 7904 and 12,159 of 1886 (this Journal, 1886, 331), which improvements relate chiefly to the employment of peat and manure as sizing agents in paper. The pulp may be coloured by means of salts of iron.

—E. J. B.

Improvements in the Manufacture of Paper from Vegetable Fibre. A. W. Hayles, Crawley. Eng. Pat. 15,697, October 1, 1890. *Ad.*

According to this invention the reed known as the *Phragmites communis* is used as the raw material. When it is intended to store the pulp for any length of time, it is mixed with boracic or salicylic acid to prevent fermentation. —E. J. B.

Improvements in Lining Boilers or Digesters used in the Manufacture of Paper Pulp and for similar Purposes. C. Kellner, Vienna, Austria. Eng. Pat. 15,930, October 8, 1890. *Ad.*

The boiler is first coated with the cement described in specification Eng. Pat. 6951 of 1890 (this Journal, 1891, 380), consisting of a paste of ground slate and silicate of soda. Upon this cement a paste is laid made of 1 part ground slate, 2 parts ground glass, and 1 part Portland cement.—E. J. B.

Improvements in Lining Boilers or Digesters used in the Manufacture of Paper Pulp and for other similar Purposes. C. Kellner, Vienna, Austria. Eng. Pat. 15,931, October 8, 1890. *Ad.*

According to this invention the boiler is lined with blocks or slabs made of the same materials as the cement described in the previous specification.—E. J. B.

Improvements relating to the Manufacture of Paper, Paste-board, and the like, and to Apparatus therefor. B. J. Beckmann, Papenburg, Germany. Eng. Pat. 16,546, October 17, 1890. *Sd.*

The improvements consist in introducing wire gauze or wire-work into the middle of a sheet of paper as it is being formed on a paper machine. The arrangement of the necessary apparatus is shown in the drawings accompanying the specification.—E. J. B.

Improvements in the Manufacture of Strainer or Knatter Plates for Straining Paper Pulp, Wood Pulp, and the like. H. B. Watson and J. S. Watson, Newcastle. Eng. Pat. 16,928, October 23, 1890. *11d.*

The improved strainer plate consists of a frame cast in bronze into which are fitted a number of plates made of an alloy of 95 parts of copper and 5 parts of tin. These latter contain the narrow slits through which the pulp is strained, and they are so arranged as to fit easily into the frame and be readily removable when necessary.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Cantharidin. F. Anderlini. Ber. 1891, 24, 1993—2000. In a previous paper (Ber. 1890, 23, 485; this Journal, 1891, 645) the author has shown that ammonia reacts with cantharidin to produce the imide $C_{10}H_{12}O_3.NH$, a body which is stable both towards the caustic alkalis and caustic baryta. The hydrogen of the imide-group in this compound can be replaced by alcohol radicals by treating the imide with alkyl iodides in presence of the carbonates of the alkalis, whilst the same products can be prepared directly from cantharidin by the action of the corresponding primary amines in methyl or ethyl alcohol solution at

150—160° C. These substituted cantharidin-imides are weak bases which do not unite with acids to form salts, whilst the characteristic physiological properties of cantharidin disappear for the most part in the substituted imides. The following imides have been prepared:—

Cantharidin-methylimide, $C_{10}H_{12}O_3.N.CH_3$

Cantharidin-ethylimide, $C_{10}H_{12}O_3.N.C_2H_5$

Cantharidin-amylimide, $C_{10}H_{12}O_3.N.C_3H_7$

Cantharidin-allylimide, $C_{10}H_{12}O_3.N.C_3H_5$

Cantharidin-phenylimide, $C_{10}H_{12}O_3.N.C_6H_5$

Cantharidin-α-naphthylimide, $C_{10}H_{12}O_3.N.C_{10}H_7$

Acetic anhydride reacts with cantharidin-imide at 230° to form the *acetyl compound*, $C_{10}H_{12}O_3.N.C_2H_5O$, which is saponified by boiling with water. It has already been shown that hydriodic acid converts cantharidin into a monobasic acid called cantharic acid, $C_{10}H_{12}O_4$. The same acid is produced by treating cantharidin with chloro-sulphonic acid; it forms rhombic crystals, which melt at 275° C. It reacts with ammonia, similarly to cantharidin, to form an *imide*, $C_{10}H_{12}O_3.NH$, melting at 187° C. Cantharic acid when heated with acetyl chloride in a closed tube to 135° C. is converted into an isomer of cantharidin, *isocantharidin*, which forms monoclinic crystals, readily soluble in alcohol, ether, and benzene, and melting at 75°—76° C. The aqueous solution of this acid when heated to boiling for some hours is transformed into a dibasic acid, which has the composition $C_{10}H_{14}O_5 + H_2O$, and to which the name *iso-cantharidinic acid* is given. It loses its molecule of water of crystallisation at 100° C. and at 163° C. gives up a second molecule of water, forming an *anhydride*, which melts at 75—76° C. and which, when boiled with water, regenerates the acid. The acid decomposes the alkaline carbonates; analyses of the *silver and barium salts*, both of which contain water of crystallisation, are given. Treated with methyl iodide, a *dimethyl ester* results, $C_{10}H_{12}(CH_3)_2O_5$. —C. A. K.

Constitution of Pinene. G. Wagner. Ber. 1891, 24, 2187—2190.

The author does not agree with Wallach's explanation of the formation of pinene glycol (pinol hydrate) by the oxidation of pinene (Ber. 1891, 24, 1524; this Journal, 1891, 850); he also considers that the constitution of pinene is most correctly represented by the formula—

which not only accounts for the behaviour of pinene on oxidation, but also gives a more plausible explanation of various other reactions of pinene, than the constitutional formula put forward by Wallach.—F. S. K.

Benzoyl-ψ-Tropine, one of the Alkaloids of Javanese Coca Leaves. C. Liebermann. Ber. 1891, 24, 2336—2345.

Benzoyl-ψ-tropine was recently discovered by F. Giesel in a small-leaved coca plant cultivated in Java. The plant contains 2 per cent of alkaloids, of which about one-twentieth consists of cinnamyl-cocaine, whilst of cocaine there is very little. Benzoyl-ψ-tropine resembles dextro-cocaine, but it has no optical activity, and its hydrochloride differs from that of *d*-cocaine in solubility and crystalline form. With potassium bichromate it yields a crystalline precipitate instead of an oily one like cocaine and *d*-cocaine. On hydrolysis it yields—not ecgonine like the other cocaine bases—but ψ-tropine, which contains one carboxyl group less than ecgonine. In a solution of the hydrobromide,

sodium carbonate produces a milky precipitate of benzoyl- ψ -tropine, which does not subsequently become crystalline. It may be extracted by means of ether, and the solution leaves on evaporation an oil which, when quite dry, solidifies into a stellate mass of crystals which melts at 49° C. The base is very soluble in all the common solvents, and its alcoholic solution is strongly alkaline. When quickly heated small quantities of the base distil unchanged.

Benzoyl- ψ -tropine hydrochloride, $C_{11}H_{13}NO(C_7H_5O)HCl$, prepared by mixing ethereal solutions of hydrochloric acid and of the free base, forms white needles, melting at 271° C. A solution of this salt gives with platonic chloride a flesh-coloured, amorphous, insoluble powder of the composition $(C_8H_{14}NO(C_7H_5O)HCl)_2PtCl_4$. The gold salt, $C_8H_{14}NO(C_7H_5O)HCl.AuCl_3$, crystallises from boiling water in yellow needles, melting at 208° C. Mercuric chloride yields with the hydrochloride a voluminous crystalline precipitate, whilst with picric acid a precipitate of fine yellow needles, with difficulty soluble in water, is obtained.

On heating with hydrochloric acid, benzoyl- ψ -tropine is decomposed into benzoic acid and ψ -tropine. This base was first prepared by Ladenburg and Roth (Ber. **17**, 151; this Journal, 1884, 328, 329) by the decomposition of hyosine. The properties ascribed by these authors to ψ -tropine and its compounds are identical, practically in all respects, with those which the author has found for his own corresponding preparations. ψ -Tropine is strongly alkaline in reaction, and has no effect on polarised light. It is readily soluble in alcohol and water. An ethereal solution yields, on evaporation, fine needles of the base, melting at 106° — 107° C. The synthesis of benzoyl- ψ -tropine from benzoic anhydride and ψ -tropine is most easily effected, the yield being very satisfactory.

Cinnamyl- ψ -tropine prepared from cinnamic anhydride and ψ -tropine melts at 87° — 88° C. It is readily soluble in cold alcohol, ether, and benzene; somewhat less soluble in petroleum spirit. The hydrochloride is prepared by passing hydrochloric acid gas into a solution of the base in ether. It is easily soluble in alcohol and water. The picrate and gold and platinum salts of cinnamyl- ψ -tropine resemble the corresponding compounds of benzoyl- ψ -tropine.

Benzoyl- ψ -tropine hydrochloride is not a true mydriatic substance; injected into the eye of a rabbit, it only produced strong local anaesthesia.

In order to arrive at the constitution of ψ -tropine, the author intends to study the action of oxidising agents upon it. If tropic acid be the product of oxidation, the relationship existing between tropine and ψ -tropine may possibly be that exhibited by the following formulae:—

If Ladenburg's assumption of the existence of an open side-chain in tropine be correct, the two formulae would be—

—H. T. P.

Conversion of Maleic into Fumaric Acid. Z. H. Skraup. Monatsh. Chem. 1891, **12**, 107—145.

It has been assumed by Wislicenus that in the transformation of maleic into fumaric acid by the action of hydrochloric acid, the maleic acid is converted into chlorosuccinic acid; this compound is then supposed to undergo a stereochemical change, and finally to split up into fumaric acid and hydrochloric acid. Many other transformations of a like nature are explained by Wislicenus in a similar manner, but his hypothesis has been called into question by Anschütz and Fittig on the grounds that in several cases the hypothetical intermediate products are quite stable under the conditions of the experiment.†

The author finds that the conversion of maleic into fumaric acid is brought about by acids, such as sulphuric, nitric, and oxalic acid, which could hardly form addition products, and also, at a certain temperature, by water under pressure. His experiments show that Wislicenus' hypothesis is certainly not tenable in its present form, although it is true that addition products play an important part in the conversion of maleic into fumaric acid.—F. S. K.

See under IV., page 915.

Action of Hydriodic Acid on Quinine; Isoquinine. E. Lippmann and F. Fleissner. Monatsh. Chem. 1891, **12**, 327—337.

It has been suggested by Skraup that, in the compounds formed by the combination of cinchonine with three molecules of hydrochloric acid and hydrobromic acid respectively, two of the molecules of the acid are combined in the ordinary way, the remaining molecule forming a true addition product with the cinchonine, one of the double bindings being transformed into a single one. According to the investigations of Koenigs and Comstock quinine behaves in a similar manner, and in the case of the compounds—

it may be assumed that one molecule of the acid combines with the base to form a true addition product.

Now, since the quinine molecule is supposed to consist of the two atomic complexes $C_{10}H_{12}NO$ and $C_{10}H_{12}NO$, and since, further, quinine and its derivatives do not combine directly with halogen acids, it would seem that the molecule of the acid is added to the complex $C_{10}H_{12}NO$. This view is rendered more probable by the fact that partially reduced phthalic acids combine directly with bromine, as has been proved by Baeyer. The following experiments show that the molecule of hydriodic acid, which is assumed to be added to the quinine molecule, is readily eliminated by the aid of alcoholic potash.

Hydriodoquinine, hydriodide. $C_{20}H_{24}N_2O_2, 3 \text{ HI}$ is deposited in yellow prisms when quinine or its hydrochloride is warmed with concentrated hydriodic acid on the water-bath for 1 to 2 hours; it is separated from the cold solution by filtration, washed with hydriodic acid and alcohol successively, and then extracted with boiling alcohol. It begins to decompose at 215° , melts at 230° , and is only sparingly soluble in cold water and alcohol.

Hydriodoquinine $C_{20}H_{24}N_2O_2, \text{HI}$, is obtained when the preceding compound is triturated with dilute ammonia and the mixture extracted with ether; it crystallises from a mixture of benzene and light petroleum in slender needles, softens at 95° , and decomposes at a higher temperature; when heated with silver nitrate it is completely decomposed with separation of silver iodide. The *platino-chloride*, $C_{20}H_{24}N_2O_2, \text{HI}, \text{H}_2\text{PtCl}_6 + 2 \text{ H}_2\text{O}$ forms small brown crystals.

Hydriodoapoquinine hydriodide, $C_{19}H_{22}N_2O_2, 3 \text{ HI}$, prepared by heating hydriodoquinine hydriodide with concentrated hydriodic acid at 100° under pressure, separates from alcohol in yellow, ill-defined crystals, and melts at 237° with decomposition; when treated with ammonia it is converted into *hydriodoapoquinine*, $C_{19}H_{22}N_2O_2, \text{HI}$, a crystalline compound, the *platino-chloride* of which has the composition $C_{19}H_{22}N_2O_2, \text{HI}, \text{H}_2\text{PtCl}_6 + \text{H}_2\text{O}$.

Isoapoquinine, $C_{19}H_{22}N_2O_2$, can be obtained by heating hydriodoapoquinine with alcoholic potash; it melts at 176° , whereas Hesse's apoquinine decomposes at 160° , but, like

the latter, it is readily soluble in dilute alkalis. The *platino-chloride*, $C_{19}H_{22}N_2O_2 \cdot H_2PtCl_6 + H_2O$, is a crystalline compound, sparingly soluble in water.

When hydriodiquinine or its hydriodic acid is boiled for some hours with alcoholic potash, it is completely converted into a base, isomeric with quinine, which the authors name *isoquinine*. This compound has properties quite different from those of Hesse's cinchonine and quinidine; it is very readily soluble in alcohol and benzene, but only sparingly in boiling water and hot dry ether; it gives the same reaction with chlorine water and ammonia as quinine and its solutions in dilute sulphuric acid and nitric acid show a blue fluorescence, which disappears on the addition of hydrochloric acid or chlorine compounds. It melts at 186° , and its specific rotatory power in 97 (volume) per cent. alcoholic solution is $[\alpha]_D^{20} = -180.8$ at 27° ($C = 0.9644$), but this value decreases with increasing concentration; isoquinine, and its salts, have an intensely bitter taste. The *hydrate*, $C_{19}H_{24}N_2O_2 \cdot 2 H_2O$, is obtained in small needles, when a solution of the hydrochloride is decomposed with ammonia, the solution extracted with ether, and the extract slowly evaporated at the ordinary temperature. The *sulphate*, $(C_{19}H_{24}N_2O_2)_2 \cdot H_2SO_4 + 10 H_2O$, crystallises in needles, and is very readily soluble in water. The *neutral hydrochloride*, $C_{19}H_{24}N_2O_2 \cdot HCl + 2 H_2O$, crystallises in needles, and is readily soluble in water, but the *acid hydrochloride*, $C_{19}H_{24}N_2O_2 \cdot 2 HCl$, is more sparingly soluble. The *platino-chloride*, $C_{19}H_{24}N_2O_2 \cdot H_2PtCl_6$, is a yellow crystalline compound. When isoquinine is treated with silver nitrate in alcoholic solution (see next column) a compound of the composition $C_{19}H_{24}N_2O_2 \cdot AgNO_3$ is precipitated.

—F. S. K.

Bergapten. C. Pomeranz. *Monatsh. Chem.* 1891, **12**, 379—392.

THE ethereal oil of the fruit-peel of *Citrus Bergamia aurantica*, which is extensively used in the making of perfumes, deposits on standing a yellowish crystalline substance, the stearopten of oil of bergamot, which has been long known under the name of bergapten or bergamot camphor, and has been the subject of various earlier investigations.

The author has carefully examined a sample of bergapten obtained from Schimmel and Co., and purified by sublimation and by crystallisation from alcohol. The pure substance melts and sublimes at 188° , crystallises in colourless, lustrous needles, and is only very sparingly soluble in boiling water, but readily in hot alcohol, glacial acetic acid, &c. Analyses, and a molecular weight determination in phenol solution, gave results agreeing with those required by a compound of the molecular formula $C_{12}H_{10}O_2$.

When bergapten is boiled with methyl iodide and methyl alcoholic potash for about five hours, two compounds are formed, one of which is insoluble, the other soluble in water. The former separates from alcohol in microscopic prisms, melts at 52° , and has the composition $C_{13}H_{11}O_2$; the latter is the potassium salt of an acid which the author names *methylbergaptenic acid*. This acid crystallises from dilute alcohol in rhombic plates, melts at 138° , and has the composition $C_{13}H_{11}O_2$; the compound melting at 52° is the methyl salt of this acid.

Ethylbergaptenic acid, $C_{14}H_{13}O_2$, can be prepared in a similar manner; it crystallises in prisms or needles, and melts at 112° .

When bergapten is fused with potash it yields phloroglucinol, and when treated with bromine it is converted into a crystalline, unstable compound which seems to have the composition $C_{12}H_7O_4Br_3$. On treating methylbergaptenic acid with sodium amalgam it yields a crystalline acid which melts at 122° and has the composition $C_{13}H_{11}O_2$.

The constitution of bergapten is not definitely established by these experiments, but it is hoped that further investigation will settle the question.—F. S. K.

Action of Hydriodic Acid on the Cinchona Alkaloids. Z. H. Skraup. *Monatsh. Chem.* 1891, **12** 431—434.

THE prospective publication of Lippmann and Fleissner's paper (see preceding page) on the action of hydriodic acid on quinine has led the author to give a brief account of the results which he and his pupils have already obtained in their investigation of the behaviour of the cinchona alkaloids and their derivatives with hydriodic acid.

Quinine, quinidine, cinchonidine, and cinchonine combine with 3 mols. of hydriodic acid forming yellow or orange-red compounds; under certain conditions a methyl group is eliminated from the quinine and quinidine molecules, and there are formed compounds of the composition—

which are soluble in potash.

The salts of the composition, $C_{20}H_{24}N_2O_2 \cdot 3 HI$, and $C_{19}H_{22}N_2O_2 \cdot 3 HI$, obtained from quinine and cinchonidine, are converted into bases of the composition $C_{20}H_{25}N_2O_2$ and $C_{19}H_{23}N_2O_2$ respectively, on treatment with warm alkalis, 2 mols. of hydriodic acid being eliminated in each case; the isomeric salts obtained from quinidine and cinchonine are converted into bases of the composition $C_{20}H_{25}N_2O_2$ and $C_{19}H_{23}N_2O_2$ respectively, on treating them with excess of alkali, 1 mol. of hydriodic acid being eliminated. The salts of the composition, $C_{19}H_{22}N_2O_2 \cdot 3 HI$, obtained from quinine and chinidine (see above) show an analogous behaviour; that obtained from quinine loses 2 mols. of hydriodic acid on treatment with potash, whereas only 1 mol. of the acid is eliminated from the quinidine salt.

Several other facts are briefly stated, the full account of the experiments being reserved for a future paper.—F. S. K.

A New Laboratory Process for Preparing Hydrobromic Acid. G. S. Newth. *Chem News*, October 30, 1891, 215.

THIS method is a synthetical one, and consists in passing a stream of hydrogen and bromine vapour over a spiral of platinum wire heated to bright redness by means of an electric current. A glass tube, about 7 inches long and five-eighths inch bore, is fitted at each end with a cork carrying a short straight piece of small tube; through each cork is also fixed a stout wire, and these two wires are joined by means of a short spiral of platinum wire, the spiral being about 1 in. long. One end of this apparatus is connected to a small wash-bottle containing bromine, through which a stream of hydrogen can be bubbled. The other end is attached to a tube dipping into a vessel of water for the absorption of the gas, or, if a large quantity of the solution is required, to a series of Woulf's bottles containing water. Hydrogen is first slowly passed through the tube until the air is displaced, when the platinum spiral is heated to bright redness by the passage of a suitable electric current. Complete combination takes place in contact with the hot wire, and the colour imparted to the in-going gases by the bromine vapour is entirely removed, and the contents of the tube beyond the platinum are perfectly colourless. The vessel containing the bromine may be heated to a temperature of about 60° C. in a water-bath, at which temperature the hydrogen will be mixed with nearly the requisite amount of bromine to combine with the whole of it. So long as even a slight excess of hydrogen is passing, which is readily seen by the escape of bubbles through the water in the absorbing vessels, the issuing hydrobromic acid will remain perfectly colourless, and therefore free from bromine; so that it is not necessary to adopt any of the usual methods for scrubbing the gas through vessels containing phosphorus. When the operation is proceeding very rapidly a lambent flame occasionally appears in the tube just before the platinum wire, but this flame is never propagated back through the narrow tube into the bromine bottle. The precaution may be taken, however, of plugging this narrow tube with a little glass wool, which renders any inconvenience from this cause quite impossible. By this method a large quantity of

bromine may be rapidly converted into hydrobromic acid without any loss of bromine, and the operation when once started can be allowed to proceed without any further attention.

Improvements in Obtaining or Separating Oxygen from Atmospheric Air. J. H. Parkinson, Manchester. Eng. Pat. 14,925, September 22, 1890. 8d.

PERMANGANATES give off oxygen when heated in vacuo, and the residue absorbs oxygen by treatment with air under pressure. The reacting material may consist of permanganate or manganate of potash or soda, preferably baked with kaolin (see following abstract), or a combination of lower manganese oxides and free alkali mixed with clay, or else pumice stone, "saturated with a solution of permanganate or with the lower oxides of manganese,"—the purport of all of which mixtures being to reduce the permanganate to a porous spongy condition. This permanganate is charged in retorts and kept at a temperature of, say, 550° C., whilst a vacuum pump draws off the oxygen and conveys it to a gas-holder. Superheated air, previously purified with caustic soda or lime, is now forced into the retort, and coming in contact with the residue consisting of "the lower oxides of manganese and probably free alkali," gives up its oxygen, whilst the nitrogen escapes into the atmosphere. The retorts are worked in series; a description of the apparatus is given, accompanied by five drawings; the details of the apparatus are fully described in Eng. Pat. 9457, 1891 (not yet published).—H. A.

Improved Process of Treating Permanganate of Potash to Produce a Spongy Porous Mass. J. H. Parkinson, Manchester. Eng. Pat. 14,931, September 22, 1890. 8d.

For the successful production of oxygen (see previous extract) it is necessary that the permanganate should be in a finely-divided condition. This is best attained by grinding together permanganate or manganate of potash or soda with, say, 15 per cent. of kaolin, mixing the mass with water into a stiff paste, in which state it is moulded into bricks. The slabs are placed on shelves within a vessel provided with a tightly-fitting lid and provided with a connection to a vacuum pump. The operation is assisted by saturating the atmosphere of the vessel with aqueous vapour, for which purpose three-quarters of an inch of water is placed on the bottom of the vessel, which is thereupon exhausted of air and gently heated, commencing at 15°–20° C., till all the water has evaporated. Under the combined action of the vacuum, and of a steadily increasing heat (up to 100° C.), the mass will bake in 3–4 hours time into a hard and porous mass.

At one part of this drying and baking operation "the communication with the vacuum pump is closed and the heat gradually applied until a pressure somewhat above that of the atmosphere is produced in the retort, by which time the water placed in the retort and the moisture of the mixture is converted into vapour."

At the end of the operation some oxygen is given off. Two sheets of drawings accompany the specification.—H. A.

Improvements in the Filling of Cylinders or other Receivers with Oxygen, Hydrogen, Coal, Oil, and other Gases or Mixtures of Gases under Pressure. J. H. Parkinson, Manchester. Eng. Pat. 18,445, November 15, 1890. 8d.

See under I., page 908.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Improvements in or Relating to Photo-Mechanical Colour Printing. F. J. Upton, London, and G. Stephens, Walthamstow. Eng. Pat. 1793, January 31, 1891. 6d.

A PHOTOGRAPHIC negative of the object to be represented is taken and developed in the usual manner. From this negative, which is of any required size, several positives are printed upon paper sensitised in different manners according to the number of colours in the object photographed; thus, a positive intended to receive the yellow shades alone of the original object is coated with potassium dichromate (15 parts), silver nitrate (5), "muriates of iron or protochloride" (5), gelatine (30), and water (45); for the red shades, with potassium dichromate (20 parts), silver nitrate (15), gelatine (20), and water (45), after floating the paper in a 10 per cent. solution of chrome alum and drying it; for the blue shades solely, with potassium dichromate (20 parts), "muriates of iron or protochloride" (10), gelatine (10), and water (60), after floating in a chrome alum solution (10 per cent.) and drying; for the black, brown, and grey shades, with gelatine (10 parts), potassium dichromate (10), and water (80) (in printing for these shades, the time of exposure varies inversely with the intensity of shade required, the positive for black being, thus, exposed for the shortest time of the three); and for "any slight tints of colour, having no body" the paper is lightly coated with a solution of gelatine (5 parts), potassium dichromate (5), alcohol (2), and water (88). The printed positives are covered with a mixture of "re-transfer ink" and palm oil, washed with water to remove the surplus ink, partially dried, and transferred to lithographic stones. The resultant impressions from these various stones upon paper, each having its requisite form, position, and colour, produce a perfect picture of the object photographed.—E. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Chemical Theory of Gunpowder. H. Debus. Annalen, 1891, 265, 257–315.

THE author discusses briefly the earlier views which were entertained in regard to the products of the explosive decomposition of gunpowder, and refers to a former paper of his (Annalen, 112, 295–298) for a fuller statement of his views on this part of the subject. He notes how Noble and Abel confirmed the conclusions of Karolyi that the quality of the products of decomposition when the powder is fired in a closed vessel is only dependent on the composition of the powder and not on the pressure developed. The quantities of the products, however, as found in different experiments and by different observers, vary greatly, but the author points out several circumstances which would account for these discrepancies, and states that both the quality and quantity of the products of decomposition depend solely on the composition of the powder. As the composition of powders is very varied, so must also be that of the products of their decomposition, and the author proceeds to develop a general equation which can be adapted to each special case, and by means of which the quantities of the different products of decomposition, the amount of heat and gas produced, and also the relative energy can be calculated, and shows that theory and facts agree, and that it is possible to determine by purely theoretical means the composition of a powder which is required to fulfil specific conditions. He assumes that the combustion is complete, and that the powder is composed only of saltpetre, sulphur, and pure carbon, the other constituents of the carbon being neglected. He also takes

the potassium sulphide formed to be K_2S_2 . The quantity of carbonic oxide formed must be determined by experiment, and this be represented by x , then the general equation for the decomposition is as follows:—

The author gives an example of the calculation of the relative potential energy of a powder by means of the formula, and accepts Berthelot's suggestion to take the product of the volume of gas evolved and the number of calories given off as a measure of the potential energy and then deduces the general principles that govern every kind of powder the quantity of gas increases and the quantity of heat decreases with the carbon and sulphur. Next follows a comparison of theory with the results obtained by N. He and Al. and H. von S. (Ann. Chem. Phys. 1890—1891), when he shows that although the latter experimenters found in all cases more gas and calories than the former, the order in which the relative potential energy of the powders follow is the same according to both observers, and agrees with theory. The author then goes on to describe a graphic representation of the quantities of saltpetre, sulphur, and carbon, which are converted into potassium carbonate, sulphate, disulphate, carbonic acid, and nitrogen, but the original article, as well as another (Annalen, 213, 40), must be consulted for explanations of the author's views and method of calculation. He shows that "when the amount of saltpetre and sulphur is constant the energy increases with the carbon, and when the saltpetre and carbon are constant it decreases as the quantity of sulphur increases." As an evidence of the insufficiency of the purely empirical methods which have been hitherto employed in determining the composition of explosives, he points out the great variations of the proportions which have been used from time to time in different countries and in different works. In Prussia military powder had the following composition in the last mentioned years:—

Year	Saltpetre	Charcoal	Sulphur
1774	75.4	13.5	11.1
84	77	12	11
90	77	12.1	11.7
94	76	12.5	11.5

The composition of the powder of the principal countries of the world may be referred to the three following types:—

	I	II	III
Saltpetre	75.0	77.0	77.0
Charcoal	13.0	12.0	12.0
Sulphur	12.0	11.0	11.0

The author states that in the same manner as the sulphur on a match causes the combustion of the wood, in gun powder the burning sulphur heats the saltpetre and charcoal to the temperature of reaction. A mixture of saltpetre and charcoal is less easily ignited than a mixture of saltpetre and sulphur, and he concludes also that a certain proportion of sulphur is necessary. In reference to the powder it is shown that theoretically the best strength powder, and this agrees with experience.—W. M.

Explosions of Powder, Dynamite, &c. Chem. Ind. 1891. 14, 279—283.

COMMENTING on an explosion which took place at a powder mill, attention is called to the necessity of carefully and at once removing powder-dust whenever it is formed, or thoroughly sprinkling the place with water.

Few explosions are reported in dynamite works, and this favourable state of affairs is attributed to the improved method of working and the more perfect construction of the cartridge machines. A most important point in these machines is to have the rammer working true in the charging cylinder.

An accident having occurred through the explosion of some frozen nitroglycerin lying in a gutter which was being scraped by an iron rake, it is recommended that all such gutters and conduits should be thoroughly washed out with warm water (about 60° C.).

Some accidents occurred in picric acid factories. In this connection it is pointed out that picric acid by itself is not dangerous, and cannot be exploded by blows, but in the form of a picrate is very dangerous. Picric acid melts at 117°, and in this state readily combines with any lime-dust, or iron oxide from rusty nails. Hence it is necessary to take special care in the construction of the drying rooms, the walls must not be whitened with lime, the acid should be dried on glass plates in wooden frames, but the latter must not be fastened with nails.

A few trivial accidents are reported from the inflammation of gun-cotton.

The manufacture of mercury fulminate and detonators gave rise to the greatest number of accidents. The old practice of using a wooden "charging spoon" is condemned and the advantages of employing one of ebonite advocated. As the latter does not shrink or warp, the holes for the copper cap and detonator cases can be bored the correct size, and thus avoid the loosening of the fulminate round the cases, which often give rise to accidents when they are removed from the spoon.

The practice of destroying fulminate residues by burning is condemned, and the method of decomposing by means of hydrochloric acid recommended. The view that fulminate is rendered harmless by treatment with caustic soda or lime and addition of sodium sulphide is unreliable, as explosive double salts are often formed. When zinc or tin is used to precipitate the mercury, the fulminic acid goes over to the other metal. The disadvantage of the hydrochloric acid method is the evolution of hydrocyanic acid which takes place; this, however, can be remedied by efficient ventilation of the room in which the decomposition is effected.

It is further recommended that the nitrous vapours which are given off when the mercury is dissolved in nitric acid, as well as those evolved from the action of the mercury nitrate on the alcohol, should be condensed as far as possible, and the permanent gases led into a high chimney. Precautions should also be taken against mercury poisoning among the workpeople.—W. M.

PATENTS.

Improvements in the Manufacture of Explosives for Industrial and Projectile Purposes. A. J. Campion, Mangrove, and J. E. Tomson-Woods, London. Eng. Pat. 15,726, October 4, 1890. 6d.

THIS invention consists, first, in the manufacture of ammonium nitrate for explosive purposes by a new process, and, second, its formation into an explosive by admixture with certain solid hydrocarbons, such as crotonite or paraffin wax, and, in some cases, sulphur and charcoal are also added.

The ammonium nitrate is thus rendered non-hygroscopic. This salt is prepared, according to the first process, by adding ammonium chloride to sodium nitrate in solution, double decomposition takes place, and the salts are separated by crystallisation. In the second method, sodium nitrate is added to calcium chloride, double decomposition occurs, and the salts are separated by crystallisation. To the calcium nitrate thus obtained ammonium sulphate or

carbonate is added, and the ammonium nitrate is separated from the precipitated calcium salt and obtained by evaporation from its solution.—W. M.

Improvements in Explosives. G. Trench, Faversham. Eng. Pat. 18,472, November 15, 1890. *Ad.*

THIS specification describes an explosive containing, say, dinitrobenzene 1 part, nitrocellulose 1 part, barium and potassium nitrates 6 parts, nitroglycerin 2 parts.

The presence of the nitroglycerin renders the substance plastic, an advantage not possessed by the explosive described in the inventor's previous patent, 18,241 of 1889 (this Journal, 1890, 1010).—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

The Measurement of the Concentration of Solutions by Means of Refractive Index. H. O. G. Ellinger. Jour. prakt. Chem. 1891, **44**, 152—157.

WHEN a substance is dissolved in a liquid, the index of refraction of the latter is changed, and the change becomes greater as the concentration increases. Very exact measurements of the degree of concentration of a solution can be carried out by making use of this fact. The "oleorefractometer" introduced by Amagat and Jean is specially adapted for such determinations. It ought to be called a "difference refractometer," since it is capable of wider use than its original name indicates. The apparatus is arranged as follows:—The collimator and telescope are placed in a fixed position, so that their axes are in line. The light after leaving the collimator passes through a layer of liquid contained in a trough bounded by two parallel glass plates, and from this into the telescope; but within the layer of liquid mentioned there is a hollow prism formed by two plane-parallel glass plates, into which another liquid can be introduced. Instead of a slit the collimator has a vertical knife edge, moveable by means of a micrometer screw. In the telescope there is a transparent plate, on which is a finely-divided scale of 100 divisions. The following is the method of finding the amount of a given substance in solution in water:—

Distilled water is first poured into the trough and prism, and a candle-flame is placed in front of the knife edge of the collimator. The field of the telescope now exhibits a bright and a dark part separated by a sharp division line. By means of the micrometer screw this line is made to fall on the null part of the scale in the field of view of the telescope. If the water in the prism is now replaced by a solution of any substance, the position of the division line is shifted, and since the refracting angle of the prism is to the left of the observer looking through the telescope, the line will shift to the right if the solution has a higher refractive index than water. In the case of common salt, if 1 per cent. shifts the division line through $7\frac{1}{2}$ divisions, 2 per cent. through 15, and 5 per cent. through 38, these numbers show the method is delicate, and that the readings are fairly proportional to the concentration. Solutions which are so concentrated that they give readings beyond the range of the apparatus (*e.g.*, common salt solutions beyond 8 per cent.) can be measured after diluting them with known proportions of water. For each substance a number can be determined which the author calls its "promillefactor;" this is the number by which the telescope reading must be multiplied in order to give the amount of the substance dissolved in 1,000 of water.

The method is rapid and easy, and can be applied to solutions in quantities as small as 2 cc. The following serves as an example and test of its use:—

A solution of sugar was made up, and contained 7.7 per cent. of sugar. This was tested (1) as prepared; (2)

diluted with an equal weight of water; (3) twice the weight of water; (4) three times the weight of water. The corresponding readings were 49, 24, 16, 12. Since the promillefactor of sugar is 1.6, these readings give 78.4, 38.4, 25.6, and 19.2 parts of sugar per 1,000; and indicate the strength of the original solution as 7.84, 7.68, 7.68, 7.68 per cent. respectively.

The addition of spirits of wine to water causes an increase in its refractive index, but this increase is not so rapid nor so regular as when a salt is dissolved. Thus the constant promillefactor would give incorrect results, and it is necessary to construct a curve or table, and work from this by interpolation. In the following table the first column gives percentages of spirits of wine by volume, and the second column the corresponding readings of the instrument:—

Percentage.	Reading.	Percentage.	Reading.
1	2	12	27½
2	4	14	32½
4	8½	16	38
6	13	18	43½
8	18	21	48½
10	22½		

The following are values of promillefactors for various substances (the water of crystallisation being reckoned in with the weight of the substance):—Sodium chloride, 1.33; potassium chloride, 1.7; ammonium chloride, 1.2; potassium carbonate, 1.45; potassium hydrocarbonate, 2.08; sodium carbonate, 1.11; sugar, dextrin, and gum, 1.6.

—D. E. J.

Burette Float for Opaque Liquids. H. Rey. Ber. 1891, **24**, 2098.

THE float described has two bulbs; the upper one, upon which is marked the line for reading, is smaller than the lower one, so as to prevent its touching the sides of the burette. The float is weighted so that the upper bulb is completely above the liquid, and therefore readings can be made with it irrespective of the character of the liquid in the burette.—D. A. L.

INORGANIC CHEMISTRY.— QUALITATIVE.

Preparation of Ammonium Sulphide. E. Donath. Chem. Zeit. 1891, **15**, 1021.

INSTEAD of the usual method of preparing ammonium sulphide, by saturating ammonia solution with sulphuretted hydrogen gas, which is troublesome and unpleasant, the author distils a mixture of ammonium chloride and solution of sodium sulphide. The sal-ammoniac, in the form of powder, is mixed with twice its weight of sodium sulphide dissolved in hot water (1 part of sodium sulphide to $2\frac{1}{2}$ parts of water), and the mixture is distilled until half the liquid has passed over. The yellow solution, so prepared, is very concentrated, and has all the properties of the ordinary reagent.—H. K. T.

The Detection of Arsenic in Metallic Iron. O. Sautermeister. Chem. Zeit. 1891, **15**, 1021—1022.

IN the German dispensatory it is directed that powdered and reduced iron shall be tested for arsenic by adding hydrochloric acid, and allowing the gas evolved, after ignition, to impinge on a porcelain dish, as in Marsh's test. The author, when testing iron in this way, added some arsenic solution in order to test the accuracy of the process, and was astonished to find that no arseniuretted hydrogen was evolved. As much as 0.1 gram. of arsenious

anhydride could be added to 1 grm. of iron without any evolution of arseniuretted hydrogen taking place. On examining the residue left after the solution of the iron, the arsenic was found as a black mass, and had evidently been reduced to the metallic state by the nascent hydrogen, as ferrous chloride does not reduce arsenious anhydride. After much searching, the author has found that this action of iron on arsenic solutions is mentioned in an article by Wohler in the *Annalen der Pharm.* of 1839. If excess of zinc be added to the iron, arseniuretted hydrogen is easily obtained when arsenic is present. The author hoped that this behaviour of arsenic in the presence of iron might allow of its separation from antimony, but on trial the latter element was found to behave in the same way as arsenic (a similar behaviour in the case of phosphorus has been proved by J. B. Mackintosh; this *Journal*, 1886, 106). In conclusion, when testing iron for arsenic, the residue left on solution of the metal in hydrochloric acid should always be examined.—H. K. T.

On the Detection of Arsenic. J. Thiela. *Annalen*, 1891, 265, 55—66.

1. *Hypophosphorous Acid as a Reagent for Arsenic.*—It is already known that arsenic is deposited in the metallic state from solution on boiling with hypophosphorous acid. The author finds that when a solution in hydrochloric acid is used the reduction takes place without boiling, and does not require a very concentrated solution of hypophosphorous acid; the method is therefore a convenient one for detecting arsenic in presence of antimony and tin. The solution to be tested may contain the arsenic as arsenious or arsenic acid; it is made strongly acid with hydrochloric acid, and commercial hypophosphorous acid is added in the proportion of 1 grm. to every 10 cc. of solution. It is best to warm the solution by placing it in a test-tube and dipping this into boiling water; the arsenic is soon precipitated as a dark-brown powder. If the solution is more dilute it may require warming for 30 minutes. When the amount of arsenic present is very small no precipitate is thrown down, but the solution turns brown in colour. In sulphuric acid solution, in absence of halogens, there is only a partial reduction, or sometimes none at all. It therefore appears that the process must be regarded as a reduction of a chloride, and not an oxide, of arsenic. In view of the fact that arsenic has a smaller affinity for iodine, it appeared likely that the iodide would be even more readily reduced. Experiment showed that the addition of potassium iodide did considerably increase the delicacy of the reaction.

With the exception of the noble metals (which are also reduced by hypophosphorous acid), copper is the only substance which is likely to lead to error; for even in dilute solution it is reduced just like arsenic. Antimony and bismuth are only reduced in concentrated solutions, and are further distinguishable by the black colour of the precipitates which they give. If the colour indicates the presence of either of these metals, the precipitate is brought into a small filter, and, without washing (for this might allow of oxidation of the arsenic) is dissolved in a few drops of a solution of bromine in hydrochloric acid. This solution will contain nearly all the arsenic and very little of the other metals, so that a repetition of the test should give a precipitate having the characteristic arsenic colour. The method cannot be used for the quantitative separation of arsenic from antimony and tin, because the precipitate oxidises very readily, and therefore cannot be washed.

2. *On the Use of Marsh's Apparatus to detect Arsenic in presence of Antimony.*—Solutions of antimony in presence of iron and hydrochloric acid do not evolve any antimonyuretted hydrogen. Since compounds of arsenic do evolve arseniuretted hydrogen under the same conditions, it appeared probable that this difference in behaviour might provide a means of detecting the one in presence of the other. Unfortunately, all commercial iron (even *ferroux reduit*) contains sulphur. This gives rise to an evolution of sulphuretted hydrogen which completely masks the arsenic test. The author met with unexpected difficulties in obtaining iron free from sulphur, but finally succeeded

in preparing it by electrolysis of iron chloride. The metal so prepared oxidises readily, and must be immediately rinsed with water, alcohol, and ether, and dried in a desiccator in vacuo. It dissolves readily in dilute acids, and when so treated in Marsh's apparatus, it gives no trace of a mirror, even when considerable quantities of antimony chloride are introduced. On the addition of arsenious or arsenic acid there is an immediate evolution of arseniuretted hydrogen. (See also previous abstract.)

3. *On the Use of Platinised Zinc in Marsh's Apparatus.*—In testing reagents for arsenic, the author generally followed the common practice of adding a few drops of platinum chloride to accelerate the solution of the tin until he found that this led to errors and diminished the delicacy of the reaction. This probably arises through the formation of a compound of arsenic and platinum. It was frequently found that hydrochloric acid, sold as "free from arsenic," appeared to be really so when tested with platinised zinc; whereas, in the absence of platinum, it produced undoubted arsenic mirrors.

4. *On the Precipitation of Arsenic Acid with Sulphuretted Hydrogen.*—The author corroborates the results arrived at by other chemists respecting this reaction. From warm acid solutions the arsenic is precipitated by a rapid stream of gas as pentasulphide, whereas a slow current of gas throws down a mixture of pentasulphide and trisulphide. On the other hand, when a rapid stream of sulphuretted hydrogen is passed through a cold solution of arsenic acid in hydrochloric acid, a bright yellow precipitate is obtained which does not consist of pure pentasulphide, but is a mixture of the trisulphide with sulphur.—D. E. J.

INORGANIC CHEMISTRY.— QUANTITATIVE.

Note on the Precipitation of Phosphorus from Solutions of Iron and Steel. R. Hamilton.

On the Analysis of Commercial Aluminium and its Alloys. F. Regelsberger. *Zeits. f. Angew. Chem.* 1891, 360—363.

THE external characteristics and behaviour, on casting, of commercial aluminium of various grades of purity are first given; then follow rapid methods for the determination of the usual impurities. The commonest of these are silicon and iron, then follow copper, lead, calcium, sodium, sulphur, and carbon. Of the impurities iron and silicon, the former is the most prejudicial. If these two impurities alone be present, and if the silicon exceed the iron in quantity, the metal may be taken as suitable for technical purposes requiring tensile strength and malleability if it contain 98 per cent. of aluminium. For a general examination of aluminium the metal is dissolved in potassium hydrate. Iron, copper, and some other metals remain undissolved, and silicon goes into solution. The residue is dissolved in sulphuric acid, the copper is precipitated by sulphuretted hydrogen or electrolytically, and the iron titrated. The alkaline solution, containing the silicon, is neutralised with hydrochloric acid, evaporated to dryness, the residue treated with water and hydrochloric acid, filtered off, ignited and weighed. It is then treated with sulphuric and hydrofluoric acids, and any aluminium dissolved out is determined in the usual way. The difference gives the silicon as silicon anhydride.

When the metal is dissolved in hydrochloric acid there is a slight loss of silicon as silicon hydride, but this solvent can be used when determining iron and aluminium. For this purpose the solution is evaporated to dryness with nitric acid or potassium chlorate, and the residue redissolved in hydrochloric acid and divided into two portions. In one of these the iron is titrated by means of stannous chloride; in the other the aluminium is separated by means of potassium hydrate, and estimated in the usual way. For exact determinations the following methods are expeditious:—

Silicon.—2 to 4 grms. of the metal, according to the quality, is dissolved in a platinum dish in six times its

weight of potassium hydrate and 50 cc. of water. The dish is covered during the first violent reaction. Afterwards the liquid is warmed until solution is complete, neutralised, and evaporated to dryness with continual stirring. The ignited and weighed silicon is to be tested with hydrofluoric acid, as above.

Iron.—3 grms. of the metal are dissolved in 50 cc. of 40 per cent. potassium hydrate in a 500 cc. flask. Then 200 cc. of dilute sulphuric acid of 1.16 sp. gr. are added, with continued shaking, and the liquid warmed until clear. After slight cooling, the iron, which is in the ferrous state, can be titrated with potassic permanganate.

Aluminium.—2 grms. of metal are dissolved in 12 grms. of potassium hydrate and sufficient water, and the solution is diluted to 200 cc. 50 cc. of the clear liquid are taken and boiled with 20 grms. of ammonium nitrate. The precipitate of aluminium hydrate is filtered by means of the filter-pump, and washed, ignited and weighed. It is then powdered and again ignited. Aliquot parts are then taken: one is boiled with water, and any alkali present estimated; the other is fused with potassium bisulphate, dissolved out in water, and any separated silica filtered off and weighed. The alkali and silica are to be deducted from the original weight of the precipitate.

The above estimation of aluminium requires time, and the author has endeavoured to find a volumetric method, but without success. Mercuric chloride is at first rapidly reduced by aluminium, but the action soon slackens, probably owing to a coating of alumina forming round the particles of metal. Methods depending on the measurement of the hydrogen evolved during solution are vitiated by the fact that the impurities, iron and silicon, also liberated hydrogen. Silicon may be rapidly estimated for technical purposes by solution of the metal in hydrochloric acid instead of potassium hydrate, the small loss of silicon as silicon hydride being neglected. For this purpose 3 to 5 grms. of the metal are dissolved in 80 to 100 cc. of hydrochloric acid of sp. gr. 1.08 in a tall, covered beaker, the solution is evaporated to dryness, and the residue washed and ignited. It is then fused with 2 to 5 grms. of mixed sodium and potassium carbonates, since it contains ferric oxide and free silicon as well as silica. The silica is then determined in the usual way in the fused mass. This method has been further simplified, as it has been found, in the course of many determinations, that the mixture of silicon, silica, and ferric oxide left on evaporating the hydrochloric acid solution has practically the same weight as the total silicon, hence the fusion with mixed carbonates may be omitted. Alloys in which aluminium forms the chief constituent, such as copper-nickel and silver-aluminium, can be analysed by the above methods. The latter, however, is preferably dissolved in aqua regia.

Silicon probably occurs in aluminium in two forms, since, when the metal is dissolved in hydrochloric acid, the residual silica always contains free silicon, no matter whether an oxidising agent has been used or not. The ratio of the combined to the free silicon can be determined by first weighing the precipitate ($\text{Si} + \text{SiO}_2 + \text{Fe}_2\text{O}_3$) left on solution of the metal in hydrochloric acid. The precipitate is then fused with mixed carbonates, and the total silica and iron determined. From these data the ratio of free to combined silicon can be calculated.—H. K. T.

Contribution to the Quantitative Estimation of Sulphur.
F. P. Treadwell. Ber. 1891, 24, 1937—1941.

SULPHIDES which are soluble in dilute acids are readily examined by determining the sulphuretted hydrogen volumetrically or, after oxidation, as barium sulphate. But the sulphur of insoluble sulphides must first be brought into a soluble form, and the author has devised the following method of doing this: A weighed portion of the sample in fine powder is added to 3 grms. of freshly reduced iron powder, contained in a small glass or porcelain boat placed in a combustion tube, through which a stream of carbonic acid is made to pass. The tube is heated to dull redness for 10 minutes, after which it is allowed to cool during the

continued passing of the gas. The boat with its contents is then placed in a 400 cc. flask through which a stream of hydrogen is sent. Dilute hydrochloric acid contained in a stoppered funnel is then allowed to drop slowly into the flask, and the sulphuretted hydrogen is collected in two absorption tubes charged with ammoniacal hydrogen peroxide, or, in certain cases, e.g. when arsenic or antimony is present in the substance, an ammoniacal solution of silver nitrate should be used. The stream of hydrogen serves to sweep out the sulphuretted hydrogen from the flask into the absorption tubes, the contents of which are then boiled for a quarter of an hour to complete the oxidation, and the solution is acidified with hydrochloric acid and evaporated on a water-bath. This latter precaution is necessary in order to separate silicic acid. The residuum is taken up with dilute hydrochloric acid, and precipitated with barium chloride. The iron powder used is the ordinary commercial "ferrom redutum," which must be heated to redness in a stream of hydrogen prior to use, and, as it always contains some sulphur, the amount of this must be determined by a blank experiment. Various determinations of sulphur in pyrites and galeua by this method agree well with those made by standard methods.—G. H. B.

Decomposition of Chrome Iron Ore by the Electric Current.
E. F. Smith. Ber. 1891, 24, 2182—2185.

THIRTY to forty grammes of caustic potash are heated to fusion in a metal crucible $1\frac{1}{2}$ in. high and 2 in. in diameter, and the heating continued until the excess of water has been removed. The crucible is then placed in a strong copper ring, which is connected with the anode of the battery employed. 0.1—0.5 grms. of the finely ground chrome iron ore (the ore need not be ground so fine as is necessary in the case of decomposition by fusion according to the ordinary methods) are transferred to the crucible, which is heated gently throughout the decomposition. The crucible is covered with a watch glass containing a hole in the centre, through which a platinum rod, connected with the cathode of the battery, passes. The current employed must not exceed one ampère, which suffices to effect complete decomposition of the ore in 30—40 minutes. Before breaking the current, it is desirable to reverse it for a short time, owing to the fact that some metallic iron is always separated on the cathode which encloses small particles of the undecomposed ore. This reversal, which renders this portion of the ore oxidisable, is readily effected by having a commutator and a Kohlrausch amperometer in circuit. When the electrolysis is complete, the contents of the crucible are digested with water, which dissolves out the excess of alkali, potassium aluminate, silicate, manganate and chromate. The insoluble portion consists essentially of oxide of iron, and should be completely soluble in warm hydrochloric acid; if there is any residue the ore has not been completely decomposed. The chromium can be determined in the aqueous extract, either gravimetrically or volumetrically, the latter method consisting in treating the solution with a known weight of ferrous ammonium sulphate, and titrating back the excess of the latter with potassium bichromate, a process which allows of the carrying out of the whole of the determination in the course of one hour. Several analytical results are given, which show variations of from 0.03—0.79 in the percentage of Cr_2O_3 found, the mean of the results agreeing well with those obtained by the ordinary fusion methods.—C. A. K.

A Source of Error in Determination of Nitrates in Water.
G. H. Bartram. J. Franklin Inst. 1891, 131, 385—386.

It is shown that in presence of relatively large quantities of chlorine, 20 per cent. of the nitrates, or, in extreme cases, even 40 per cent., may fail to be recorded by the use of the phenol sulphonic acid process unless the precaution be taken to use freshly prepared phenol sulphonic acid, or to remove the chlorine. Thus, water containing 20 parts of chlorine

to 0.5 parts of nitrogen gave the following decreasing quantities of nitrogen as the age of the solution increased:—

N found.	Age of Reagent.
0.5	Freshly prepared.
0.5	1 day old.
0.45	2 days old.
0.42	13 days old.
0.40	17 days old.
0.40	27 days old.

Correct figures were obtained, however, even when the phenol sulphonic acid had been kept for 18 months, providing that the chlorine did not much exceed the nitrogen of the nitrates.—T. L. B.

ORGANIC CHEMISTRY.—QUALITATIVE.

Optical Analysis of Butter and its Substitutes. H. O. G. Ellinger. Jour. Prakt. Chem. 1891, 44, 157–159.

THE authors have investigated the optical behaviour of butter and its substitutes by means of the oleo-refractometer described on page 949. The experiments were carried out at a temperature of 15°, and for this purpose an outer trough containing warm water, and protected by felt, was employed. The inner trough was filled with a normal oil recommended by Amagat and Jean, and at first the prism was also filled with the same oil. On substituting the specimen of butter for the oil in the prism, the division line shifts to the left, showing that butter has a smaller index of refraction than the oil. After each experiment the prism must be emptied and cleaned out with alcohol and warm water, before a fresh specimen is introduced. The authors examined 510 samples of pure Danish butter, as well as commercial margarin. Before deciding whether the method could be used for detecting adulterations, it was necessary to find the extent to which the readings given by pure butter varied. These variations naturally depend upon the feeding-stuffs used, the nature of the neighbourhood, and the time of the year. With respect to the latter, the following may be taken as average readings made at the seasons mentioned:—

(a.) February, to June,.....	30.5
(b.) September and October.....	27
(c.) November.....	30.5
(d.) December,.....	34

From a further discussion of the separate measurements the author concludes that specimens of pure butter may give readings varying from 23 to 35.

The different kinds of margarin occurring in commerce contain different percentages of butter, and therefore give various readings. The specimen examined which contained least butter (given as $\frac{1}{2}$ per cent.) gave a reading of 8. When pure butter corresponding to a high reading of 35 is mixed with equal parts of such margarin, the mixture gives a reading of 21 $\frac{1}{2}$, which is lower than the lowest limit (23) given above for pure butter. Hence the method is capable of indicating adulteration with margarin to the extent of 15 per cent. and over. —T. L. B.

On the Methods of Examining Olive Oil for Earth-Nut Oil. Holde. Mitth. Kong. techn. Versuchs. Berlin, 1891, 9, 105–107.

THE author criticises the various methods, pointing out that the method of Marie by crystallising arachidic acid from a mixture of the acids dissolved in 90 per cent. alcohol is not reliable. He points out a method of Peters (a modification of the above), which is as follows:—A mixture

of 2 cc. of the acids is cooled with 2 cc. of alcohol to 10°–11° C. for half an hour. If earth-nut oil is present, tiny clusters of crystals form on the sides of the tube, but if the olive oil is pure, no crystals separate: if now the alcohol be half evaporated, away turbidity occurs at 18°–20° C. in case earth-nut oil is present. This modification of Peters's seems, however, not to give reliable results. In the Paris Laboratory, separation of potassium arachidate at low temperatures from the saponified oil is taken as indication of the presence of earth-nut oil; but this method also the author considers to be altogether uncertain in its action.

The best means of detecting the admixture he considers to be the adoption of Renard's method (Zeits. f. Anal. Chem. 1873, 231). 10 grms. of oil are saponified, the fatty acids are freed by means of hydrochloric acid, dissolved in 90 per cent. alcohol, and the lead salts precipitated with acetate of lead. The precipitate is extracted with ether, whereby the oleate is removed, the residue consisting then chiefly of lead palmitate and arachidate, which are now decomposed by hydrochloric acid. The fatty acids are dissolved in 50 cc. of warm 90 per cent. alcohol, and carefully crystallised. The arachidic acid separating is filtered off and washed with 70 per cent. alcohol. It is then dissolved off the filter by hot alcohol, and so brought into a tared dish from which the alcohol is evaporated; the acid may then be weighed. Note must be taken of the acid dissolved by the alcohol used for washing purposes. Total arachidic acid obtained should melt at 70–71° C. (it contains some palmitic acid). So long as acid of this melting point separates from the alcoholic solution crystallisation must be continued.—T. L. B.

Volatile Organic Matter in Potable Water and a Simple Method of Estimating Dissolved Fixed and Volatile Organic Matter in Water. W. C. Young.

See pages 883–887.

The Eschka Method of determining Sulphur in Coal. J. Rothe. Mitth. Kong. techn. Versuchs. Berlin, 1891, 9, 107–109.

IN order to determine the completeness of the method of Eschka (see this Journal, 1889, 361), the results obtained with it are compared with results obtained by the combustion method of Sauer (this Journal, 1890, 330). The conclusion arrived at is that no loss of sulphur takes place, the results being quite equal to those obtained by Sauer's process, which is more inconvenient.

A proposal is made to use porcelain crucibles for the roasting, which may be accomplished in a muffle in half an hour. A number of roastings may be performed together in one muffle, and furthermore there is no liability to contamination with sulphur from the gas flame.—T. L. B.

The Separation of Resin from Fatty Acids. J. Arthur Wilson. Chem. News, Oct. 23, 1891, 201–205.

THE detection of resin and its separation from fats and oils was at one time a very difficult problem to the analyst, and in many cases was impossible. Amongst many processes we have those of Henderson, Burford, and Gladding, the latter of which has found the greatest favour. It suffers from one very serious defect, however, and that is the correction for solubility of the fatty acids and silver salts in ether. This is a very variable factor, and, of course, is dependent on the nature of the fatty matter used in the fabrication of the soap. With small quantities of resin the error thus introduced may be as much as 20–30 per cent., but of course in soaps of high resin content—say 20 per cent.—the error diminishes.

R. Williams (Analyst, 15, 190) obtained very good results by the process; thus, in a soap which actually contained 30.0 per cent. of resin, he obtained 30.7 per cent., but no mention is made as to whether the amount remaining

in the lyes, after precipitation of the soap, was determined. As to the simple detection of resin, no doubt the best test is to boil the dry fat or fatty acids (10 drops) with 5 cc. acetic anhydride, cool, and add 2 drops of pure sulphuric acid (1·84 sp. gr.), when the reddish-violet colour due to resin is easily observed, 1 per cent. of which can thus be detected.

It seems that all the above processes must make way for the admirable process of Twitchell (Analyst, Oct. 1891), who found that whereas fatty acids are, as is well known, converted into neutral ethers on passing dry hydrochloric acid gas into their alcoholic solution, the acids constituting resin are not attacked. The process obviously may be either gravimetric or volumetric, but chemists will prefer the latter on account both of speed and accuracy. The description of the process is as follows:—2·5 to 3 grms. of the dried fatty and resin acids are dissolved in from 25—30 cc. of perfectly absolute alcohol, and a current of dry hydrochloric acid gas passed in constantly. The flask containing the mixture must be kept cool by immersion in cold water. When the etherification is complete the ethers separate and the gas is no longer absorbed. The flask is removed, corked well, and allowed to stand half an hour. It is diluted with about 100 to 125 cc. hot water, then cooled, transferred to a separating funnel, and agitated with 75 cc. of ether. The aqueous layer is removed, and the ethereal layer washed with cold water till neutral to delicate litmus solution (twice always is sufficient). The ethereal liquid is received in a flask, the separator washed out with about 50 cc. of neutral spirit, and the whole titrated by standard alcoholic alkali, using phenolphthalein as indicator. The alkali should be standardised by an accurate solution of half-normal HCl, and should be either one-fifth or one-half normal, according to the amount of resin in the fatty acids. Taking the mean combining weight of resin as 347, then the percentage is easily calculated; it is reported both on 100 of dry fatty matter and on 100 of soap.

Twitchell's test experiments are eminently satisfactory, and the author confirms them by his own tests:—

1. Sample of distilled fatty acids containing no resin, when treated as described, showed 0·7 per cent. resin.

2. The above distilled fatty acids, to which were added common resin to the extent of 22·5 per cent. showed, when treated as above described, 23·3 per cent. of resin, which, after deducting the 0·7 per cent. found in No. 1, gives exactly 22·5 per cent., or the amount which was added.

3. Soap made from palm oil and other fats, but no resin, gave 0·8 per cent. resin.

4. Another soap made from fatty matter of unknown origin, but no resin, gave 1·0 per cent. resin. This, it should be observed, was of a dark colour, and evidently contained some altered or oxidised oily matter.

5. Soap which showed by Gladding's test 6 per cent. of resin, gave 4·9 per cent. by Twitchell's process.

The above results are all that may be desired, and the author has now to show how the process may be still further shortened without any sacrifice of accuracy. This can be done by leaving out the washing and dissolving in alcohol direct. A few drops of methyl orange are then added and alkali, till neutral to this indicator; phenolphthalein is then added, and the titration completed as before. The alkali required in the first case is for the neutralisation of the free hydrochloric acid, and is of course neglected. That required to neutralise to phenolphthalein is of course due to the resin, and is calculated as such.

The Estimation of Combined Alkali in Soap. J. Arthur Wilson. Chem. News, Oct. 23, 1891, 205.

THE writer, who was the first to point out the error attendant on the use of the alcohol method of determining free caustic alkali in soap (Chem. News, 49, 280; this Journal, 8, 479), advised, when both free fat and free caustic alkali are present simultaneously, the adoption of the following method:—

Determine, firstly, the total alkali in the usual manner. Then determine the amount of alkali required to neutralise the isolated fatty and resin acids from a weighed quantity of the soap. Obviously the difference is the alkali present

as hydrate, carbonate, or silicate of soda, &c. In the same paper above mentioned the following sentence occurs:—"Supposing palmnut, or cocoanut oil to have been used in the fabrication of the soap, the determination of the Na_2O required to neutralise the fatty acids becomes inaccurate, owing to the solubility of the lower fatty acids; hence another complication arises. The error, of course, may be of greater or less extent, according to the nature of the fatty matter of the soap." Fortunately, this error can be completely excluded by operating in a very simple manner as follows:—

1. The alkali, in all forms, is determined by titration with standard acid in the usual manner.

2. Another weighed quantity of the soap is decomposed in an Erlenmeyer flask with a slight excess of dilute H_2SO_4 , and the flask kept on the water-bath till the fatty acids separate quite clear. The flask is then placed in ice-water to cool, and then filtered. The fatty acids are washed three times successively with 250 cc. of boiling water and allowed to cool each time and filtered. The united filtrates are diluted to 1 litre, and 500 cc. placed in a clear white beaker and tinted with methyl orange; N 10 alkali is then dropped in till the liquid acquires the usual colour, after which a little phenolphthalein is added, and the addition of standard alkali continued till a permanent pink is established. The number of cc. used in the latter titration are due to the soluble acids, and are calculated to caprylic acid. The fatty acids in the flask, and any little on the filter are dried and weighed, and then dissolved in alcohol, and titrated with N 2 alcoholic alkali. The alkali so used, together with that required for neutralisation of the soluble acids, and deducted from the total alkali, gives the alkali existing in other forms than as soap.

Of course, if desired, the soap may be decomposed with standard H_2SO_4 , and the alkali required to neutralise the methyl orange noted, which, deducted from the total acid used, would give the acid equivalent to the alkali existing in all forms. In this manner we get—

Total alkali.
Combined alkali.
Insoluble fatty acids.
Soluble fatty acids.

The following examples illustrate the method:—

No. 1.—Soap from Cocoa-nut Oil and other Fats (Highly Watered). Total Alkali by Titration, 2·06 per cent. Na_2O .

	Grms.	Per Cent.
Weight of soap taken.....	17·145	
Weight of insoluble fat acids.....	2·29	= 13·35
Cc. of N 2 alkali to neutralise.....	16·1	= 8·05 normal.
Cc. of N 10 alkali to neutralise soluble acids.....	4·2	= 0·42 normal.
Cc. of N 10 alkali to neutralise soluble acids.....	4·2	= 0·42 normal = 0·36 per cent. soluble acids (= caprylic).
Total alkali used for both soluble and insoluble fatty acids, cc. = 8·47 normal.		
$\frac{8 \cdot 47 \times 0 \cdot 031 \times 100}{17 \cdot 145}$		= 1·53 per cent. combined alkali.

	Per Cent.
Total alkali (Na_2O).....	2·06
Combined alkali (Na_2O).....	1·53
Uncombined.....	0·53
Soluble fatty acids.....	0·36 = caprylic.
Insoluble fatty acids.....	13·35
Total fatty acids.....	13·71

No. 2. French Scouring Soap. Total Alkali by Titration, 7·037 per cent.

	Grms.	Per Cent.
Weight of soap taken.....	5·889	
Weight of insoluble fatty acids.....	2·005	= 34·06
Cc. of N 2 alkali to neutralise.....	18·05	= 9·025 normal.
Cc. of N 10 alkali to neutralise soluble acids, 10·7 = 1·07 normal = 2·6 per cent. caprylic acid.		
Total alkali used for both soluble and insoluble acids = 10·1 cc. normal = 20·2 N 2.		
$\frac{20 \cdot 2 \times 0 \cdot 0155 \times 100}{5 \cdot 889}$		= 5·32 per cent. combined alkali.

	Per Cent.

The Absorption of Bromine by Fatty Bodies. Schlagdenhauffen and Braun. *Monit. Scient.* 1891, 5, 591—600.

THE authors criticise Levallois' method for the determination of the bromine absorption coefficient of fats and oils, and state that its use will inevitably lead to the most erroneous results. This is so for the following reasons:—In the first place, bromine water, which is used volumetrically in the process, parts so readily with its bromine that it may alter greatly in strength during the time required to perform an analysis. Secondly, Levallois entirely neglects the amount of bromine absorbed by the alcohol used as a solvent for the fatty acid during titration. Experiments are quoted to show that the quantity of bromine taken up by alcohol is very considerable, and that it varies with the experimental conditions. These sources of error may be completely eliminated by the process of Mills and Snodgrass (this Journal, 1883, 436—436).—H. T. P.

The Hübl Iodine Equivalent Method. Holde. *Mith. Konigl. techn. Versuchs.* Berlin, 1891, 9, 81—100.

THIS method for the examination of oils and fats has led to a great deal of discussion, owing to the fact that there is great difficulty in obtaining concordant results. Hübl, in his original communication (this Journal, 1884, 641), recognised some of the uncertain points, and indicates the necessity of a sufficient excess of iodine. He recommends that 0.2—0.3 gm. of a drying oil, or 0.3—0.4 gm. of a non-drying oil should be used. This should be dissolved in 10 cc. of chloroform, and then 20 cc. of iodine solution, made by dissolving 25 grms. of iodine and 30 grms. of mercuric chloride in a litre of alcohol, should be added; in case decolourisation takes place 5—10 cc. more of this solution should be added; after which the whole must stand for 1½—2 hours. At the end of this time, after addition of potassium iodide, and water, titration with sodium thiosulphate is to be performed. Immediately before or after the experiment, he says, 10 cc. of the iodine solution itself must be titrated with thiosulphate for standardising purposes.

Dietrich (*Helfenbergers Ann.* 1886) and Herz (*Rep. f. analyt. Chem.* 1886, 605) gave the iodine numbers for a number of oils and their mixtures, shortly after which Schweissinger (*Pharm. Centralhalle*, 1887, 117), pointed out that these numbers varied with the concentration of the iodine solution, stronger solutions giving higher results than weaker ones.

Next Benedikt (*Zeits. f. Chem. Ind.* 1887; also this Journal, 1888, 591) pointed out that the fact of the solution remaining brown was not necessarily an indication of there being an excess of iodine present; he recommended for drying oils 50 cc. of iodine solution for 0.30—0.36 gm. of the oil, and 25 cc. of iodine solution to 0.15—0.18 gm. of oil. Merckling (*Chem. Zeit.* 1887, 11) recommended that iodine solution and sublimate solution should be kept separate until required for use; and showed that the duration of experiment and the concentration of the solutions do not affect the results in the case of non-drying oils. Brüche (*Apoth. Zeit.* 1890, 5, 493), found that the iodine numbers after two hours' action had not yet attained a maximum, but that this maximum was reached at the end of 24 hours. (See also this Journal, 1886, 309.)

In the present thesis Holde examines the questions as to what excess of iodine solution of given concentration is necessary for obtaining concordant results, and what influence variations in the concentration of the iodine solution have, equal excesses of iodine being used in the various experiments. From a large number of experiments, the results of which he gives in a comprehensive series of

tables, it would seem that Benedikt's excess (30 per cent.) is insufficient, but that constant results are only obtained with most oils by an iodine excess amounting to 65—70 per cent. For about 0.3 gm. of a non-drying oil, therefore, an initial addition of 50 cc. of iodine solution is necessary, and for 0.2 gm. of a drying oil, 60 cc. With regard to the concentration of the iodine solution, the experiments tend to show that for the examination of linseed oil the solution should be as strong as possible, and at most eight days old, whilst for olive oil and rape-seed oil 50 cc. of the solution works well, providing the solution is not more than 14 days old; the solution may be used in the case of these latter oils, however, up to three months, providing that an excess of 70 per cent. of iodine is always present. As regards time, two hours prove to be quite sufficient for the experiment.

The author formulates his conclusions into the following method for working the process:—

0.3 gm. of non-drying oil, or 0.2 gm. of drying oil, is weighed out and dissolved in a flask of about 300 cc. capacity by the aid of 18—20 cc. of chloroform. To the non-drying oil 50 cc. of iodine solution, not more than 14 days old, are added, to the drying oil 60 cc. of a solution not older than eight days. Two samples of an oil should be treated alongside each other. Action is allowed to take place for two hours. At the beginning of the experiment 50 cc. of iodine solution are titrated with sodium thiosulphate after addition of 40 cc. of a 10 per cent. solution of potassium iodide and of starch in a well-stoppered bottle; 50 cc. of iodine solution are also run into a second well-stoppered bottle, to be titrated at the end of the experiment: the mean of these two titrations is taken as correct. After the oil reaction mixture has stood for two hours, it is shaken up with 40—50 cc. of 10 per cent. potassium iodide, 120 cc. of water are then added, and titration with sodium thiosulphate is performed. If the chloroform solution of the oil should become turbid during the experiment, more chloroform must be added. A table in the original paper shows the results obtained with various oils as compared with the results of previous observers.

The numbers given are, for—

Linseed oil.....	179—180
Hemp-seed oil.....	175
Poppy oil.....	139—143
Sesam ^e oil.....	106—109
Cotton-seed oil.....	110—115
Common rapeseed oil.....	100—108
Refined rapeseed oil.....	100—107

The author determined the iodine number for a sample of supposed pure oleic acid; using the method as suggested by Hübl, almost the theoretical number was obtained, but in presence of larger excesses of iodine higher numbers were obtained, which became constant when the excess of iodine rose to 65 per cent. He concludes, since also the specific gravity, 0.905, does not agree with that given by Reilstein (0.898) for pure oleic acid, that the specimen obtained was not pure, and he has in hand the preparation of a quantity of pure oleic acid, with which further tests will be made.

On account of the wide differences between the numbers for drying and non-drying oils the author considers that the method is of the highest utility in aiding in the detection of mixtures, when used in conjunction with determination of the saponification equivalent, and of the specific gravity, and index of refraction, and with a study of the action of sulphuric acid. A table is given of the saponification equivalent, iodine number, fluidity, specific gravity, and index of refraction of a number of oils and their mixtures. Study of a Method for the Quantitative Determination of Sucrose, Invert Sugar, or Levulose. Part II. F. G. Weichmann. The School of Mines Quarterly, 1891, **12**, 249—256. For Part I. see School of Mines Quarterly, 1890, **11**, No. 3.

The experiments were made in order to determine the conditions which affect the destruction of levulose by boiling with hydrochloric acid.

The acid used was six times normal strength and 0.25 grm. sugar was taken for every experiment.

I. Invert sugar was boiled down with 60 cc. acid. In four hours the entire reducing power was equivalent to the destruction of the whole of the levulose. If more acid is used, the time necessary to destroy the same amount of sugar is proportionately reduced.

II. Dextrose was boiled with 60 cc. acid. The diminution of the reducing power of the solution was not very marked at first, but quickly increased with the time; in six hours about one-third of the dextrose was destroyed. Increase of acid proportionately diminished the time necessary to produce a given reduction.

III. Levulose was boiled with 60 cc. acid. In three hours half of the levulose was destroyed, in six hours nearly 90 per cent. was destroyed. If more acid was used the time necessary to produce a given reduction was proportionately reduced.

IV., V., and VI. Invert sugar with varying proportion of dextrose or levulose added were boiled with the same acid. These experiments showed that the amount of levulose destroyed in a given time depended on the proportion of the two sugars present.

It is evident from these experiments that a method of analysing a mixture of dextrose and levulose, based on the destruction of the levulose by boiling with hydrochloric acid, is untrustworthy.—A. L. S.

ANALYTICAL AND SCIENTIFIC NOTES.

The Cause of the Difficult Solubility of Chemically Pure Zinc in Acids. J. M. Weeren. Ber. 1891, **24**, 1785—1798.

THE author maintains that chemically pure zinc, as well as other chemically pure metals, are difficultly soluble in acids because the metals become coated at the moment of immersion with an adherent film of hydrogen, which, under normal conditions, prevents further action. In proof of this view, it was found that chemically pure zinc in contact with dilute sulphuric acid of sp. gr. 1.0575 (1:20) was scarcely attacked, but on removing the atmospheric pressure the adhering hydrogen left the surface of the zinc, and solution of the metal was rapid so long as the vacuum was preserved, but ceased again with restoration of the pressure. It was found also that increase of temperature up to 98° C. causes a very small increase of chemical action, but on reaching actual boiling at 2 degrees higher, the action became energetic, but was checked when boiling ceased. The presence of oxidising agents in the acid, such as chromic acid or hydrogen peroxide, caused very energetic action by preventing the formation of the hydrogen film. Parallel experiments were made with impure zinc, and the results of the whole may be summarised in the following table, the acid used being dilute sulphuric acid (1:20), each experiment lasting 30 minutes, and a stick of zinc of 12 grms. being used.

Description of Experiment.	Chemically pure Zinc.		Impure Zinc.	
	Zinc dissolved.	Relation.	Zinc dissolved.	Relation.
Dilute sulphuric acid alone.	Grms. 0.0050	1	Grms. 1.3422	1
Dilute sulphuric acid in vacuo.	0.0331	6.6	1.2063	0.89
Dilute sulphuric acid at 100° C. with ebullition.	0.1221	24.4	5.9504	4.4
Dilute sulphuric acid at 100° C. without ebullition.	0.0078	1.6	6.0177	4.5
Sulphuric acid + chromic acid.	0.8703	175.0	8.7053	6.5
Sulphuric acid + hydrogen peroxide.	1.5301	306.0	1.6599	3.5

Similar results were obtained with cadmium, cobalt, nickel, iron, and aluminium. In the case of impure zinc or other metal the hydrogen, according to the author, is all evolved in the neighbourhood of the impurity, and a protecting film of hydrogen is not formed on the zinc, consequently a difference in the conditions of experiment does not greatly alter the amount of chemical action.

—G. H. B.

On the Compounds of Platinum Carbonoxide. F. Mylius and F. Foerster. Ber. 1891, **24**, 2424—2443.

IN experimenting on the preparation of pure platinum the authors have made some observations on the remarkable volatile compound of platinum chloride with carbon monoxide which were described by Schützenberger in 1868 (Ann. Chim. Phys. **15**, 100, and **21**, 350). This observer recognised the existence of three compounds, PtCl₂.CO; PtCl₂.2 CO; and 2 PtCl₂.3 CO in the product of the reaction between chlorine carbonic oxide and platinum sponge at a temperature of 250°. All these substances are decomposed in contact with water into metallic platinum, hydrochloric acid, carbonic acid, and, in the case of the two last, also carbonic oxide. They also unite with other substances to form additive compounds, and the authors have investigated some of these, as well as the properties of the original substances. PtCl₂.CO was prepared by the method described by Schützenberger, and was freed from the other two accompanying compounds by digestion for some time in concentrated hydrochloric acid, which decomposes them. The substance PtCl₂.CO forms the starting-point for the preparation of the substances investigated. It is a powerful reducing agent and precipitates silver from silver nitrate solutions. Alkalis decompose it with separation of platinum black. It has a feebly basic character and forms a soluble compound with hydrochloric acid, which could not, however, be separated from solution; but the double salts with sodium, potassium, ammonium, and zinc chlorides are crystalline and of yellow colour, but so easily decomposed that their preparation is difficult. The double chlorides with organic bases are much more stable, and the double chloride of amylamine and platinum carbonoxide, COPtCl₂.C₅H₁₁NHCl forms yellow leafy crystals very soluble in alcohol and acetic ether, less so in ether, benzene, and chloroform, and dilute hydrochloric acid, but water decomposes it. It melts at 184°. The aniline and pyridine double salts were also prepared, whilst the quinoline double salt was so stable as to be soluble in warm water without decomposition.

The carbon in these compounds may be determined by elementary analysis, but the authors have devised an alternative method by the direct measurement of the carbonic oxide which is evolved on treating these compounds with a solution of potassium cyanide. The reaction proceeds according to the typical equation—

and the evolved carbonic oxide is measured by absorption in cuprous chloride.

The corresponding bromine compound is obtained by treating the chlorine compound in hydrochloric acid solution with hydrobromic acid, and is obtained in a pure form by recrystallisation from hot benzene in orange-red needles, melting at 181—182°. The iodine compound is obtained in a similar manner, but the product must be evaporated to dryness, and the residue extracted with hot benzene in order to obtain the substance in a pure condition. COPtI_3 forms red crystals resembling chromic acid, and melt at 140—150°. It is stable in the air and only slowly decomposed by water, but is decomposed readily like the chloride by alkalis and by potassium cyanide. The corresponding cyanogen compound could not be isolated, owing to its very unstable character, but the double sulphocyanide $\text{COPt}(\text{CNS})_2$, KCNS was obtained in the form of small yellow crystals, easily soluble in alcohol. No fluoride could be prepared. By passing sulphuretted hydrogen through a hydrochloric acid solution of platinumous chloride, carbon oxide, a brownish-black precipitate is obtained, which contains carbon oxide, and which the authors conclude, after examination, to be COPtS . Attempts to form the oxide COPtO were only partially successful, and it could not be isolated in a pure condition. In all these compounds it would appear that the group PtCO plays the part of a dibasic radicle similar in its affinities to platinum.—G. H. B.

Actions of Heat on Solutions of Salts of Chromic Oxide.

New Books.

THE ALKALI MAKERS' HANDBOOK. Tables and Analytical Methods for Manufacturers of Sulphuric Acid, Nitric Acid, Soda, Potash, and Ammonia. By GEORGE LUNGE, Ph.D., and FERDINAND HARTER, Ph.D. Second edition, enlarged and thoroughly revised. London: Whittaker and Co., 2, White Hart Street, Paternoster Square; George Bell and Sons, York Street, Covent Garden. 1891.

As is explained in the Preface, the size to which this work has grown, and the size of the page adopted, have justified the adoption of the term handbook rather than that of pocket-book. It is now an 8vo. volume, bound in cloth, containing 181 pages of subject-matter, preceded by Prefaces to the 1st and 2nd editions, a Note with regard to temperature scales adopted (Centigrade unless otherwise stated), atomic weights, &c., the Table of Contents, and followed by an Addendum, an Erratum, and the Alphabetical Index. A considerable number of new methods of analysis have been introduced in this new edition (this Journal, 1890, 1013). It is also announced that the tables of Kolb and Carus, contained in the 1st edition, have been now replaced by the new tables for specific gravities of sulphuric, hydrochloric, and nitric acid, and of liquor ammonia, constructed by one of the authors in conjunction with his assistants. The text is divided into GENERAL TABLES and the SPECIAL PART. In the latter the following subjects are treated of, both as regards tabulated matter and analytical details:—1. Fuel and Furnaces. 2. Sulphuric Acid Manufacture. 3. Salt-cake and Hydrochloric Acid. 4. Bleaching Powder and Chlorate of Potash. 5. Soda Ash Manufacture. 6. Sulphur Recovery (Chance Process). 7. Nitric Acid Manufacture. 8. Potash Manufacture. 9. Ammonia Manufacture. APPENDIX. Devoted to—A. Preparation of Standard Solutions. B. Rules for Sampling.

C. Comparison of the Hydrometer degrees. D. Value of Alkali per ton. The text is illustrated by 12 well-executed wood engravings.

The price of the handbook is 10s. 6d. Strongly bound in half-leather, 12s.

CHEMISCHER-KALENDER, 1892. Ein Hülfsbuch für Chemiker, Physiker, Mineralogen, Industrielle, Pharmaceuten, Hüttenmänner, u. s. w. Von DR. RUDOLF BIEDERMANN, Dreizehnter Jahrgang. Mit einer Beilage. Berlin: Verlag von Julius Springer, 1892. London: H. Grevel and Co., 33, King Street, Covent Garden.

This well-known work, is one of pocket-book form and dimensions, is strongly bound in cloth, price 3s. It contains almanack for 1892 inside the cover, and also a table of frequently-used Atomic weights and their multiples. After the title page, then follows the Preface, in which is pointed out the various improvements and novelties introduced in the present edition. Thus, the table of the Coal tar colours is much enlarged, whilst that of the reactions of the Fatty bodies had to be taken over and completed by the editor, owing to the sudden death of Dr. Schädler. After the Table of Contents, a Chronological table of the principal events from the History of the Sciences, especially Chemistry. Then follows the Notebook Calendar with its blank spaces for the different days of the year, and after this 30 pages of blank paper ruled, with four pages unruled, for memoranda, &c. Then comes the Tabulated matter, comprising tables of the most useful kinds: Specific gravities of Gases and Liquids. Salts, Alcohols. Tables of Solubility. Properties of Chemical substances. Analysis. Volumetric Analysis. Spectrum Analysis. Gas Analysis. Physiological Chemical Analysis. Technical Chemical Investigations, relating to:—I. Water. II. Assaying. III. Fuels. IV. Sulphuric acid. V. Alkali. VI. Chloride of lime. VII. Nitre and Explosives. VIII. Starch and Sugar. IX. Colours. X. Fats and Oils. XI. Tanning Agents. XII. Ceramics. XIII. Glass. XIV. Mortars and Cements. Mineralogy.

BEILAGE ZUM CHEMISCHER-KALENDER, 1892.—Contains an assortment of further useful tables of a more pronounced technological character, commencing with one of the leading foreign money currencies. II. A series of Mathematical tables. III. Another on Weights and Measures. IV. A series on Heat and Cold Measurements, &c.

A HANDBOOK OF INDUSTRIAL ORGANIC CHEMISTRY. Adapted for the Use of Manufacturers, Chemists, and all interested in the Utilisation of Organic Materials in the Industrial Arts. By SAMUEL P. SADTLER, Ph.D. Philadelphia: J. B. Lippincott Company. London: 10, Henrietta Street, Covent Garden.

The present work is designed "within the compass of a moderate-sized octavo, to take up a number of the more important chemical industries, or groups of related industries, and to show in language capable of being understood, even by those not specially trained in chemistry, the existing conditions of those industries."

The price of the book is 11. 5s., and in its compass it includes the Preface, Table of Contents, List of Illustrations, List of Diagrams, Text covering 499 pages, and the Alphabetical Index. The whole is exceedingly well illustrated with 127 excellent wood engravings and 19 diagrams.

Chap. I. treats of the Petroleum and Mineral Oil Industry. II. The Industry of the Fats and Fatty Oils. III. Industry of the Essential Oils and Resins. IV. The Cane-Sugar Industry. V. The Industries of Starch and its Alteration Products. VI. Fermentation Industries: A. Nature and Varieties of Fermentation; B. Malt Liquors and the Industries connected therewith. VII. Milk Industries. VIII. Vegetable Textile Fibres: A. Paper-making; B. Gun-Cotton, Pyroxiline, Collodion, and Celluloid. IX. Textile

Fibres of Animal Origin. X. Animal Tissues and their Products: A. Leather Industry; B. Glue and Gelatin Manufacture. XI. Industries based upon Destructive Distillation: A. Destructive Distillation of Wood; B. Destructive Distillation of Coal. XII. The Artificial Colouring Matters: I. Raw Materials; II. Process of Manufacture; III. Products; IV. Analytical Tests and Methods; V. Biography and Statistics. XIII. Natural Dye Colours. XIV. Bleaching, Dyeing, and Textile Printing.

APPENDIX.—I. The Metric System. II. Tables for Determination of Temperatures. III. Specific Gravity Tables. IV. Alcohol Tables.

QUANTITATIVE CHEMICAL ANALYSIS. Adapted for Use in the Laboratories of Colleges and Schools. By FRANK CLOWES, D.Sc., F.I.C., and J. BERNARD COLEMAN, F.I.C. London: J. and A. Churchill, 11, New Burlington Street. 1891.

OCTAVO volume, bound in cloth, price 7s. 6d. It contains Preface, Table of Contents, List of Books of Reference recommended, subject-matter illustrated by 83 wood engravings, and Alphabetical Index. The work is divided into five parts and an Appendix. Each part is then subdivided into sections, and the items in these are not only paged, but also paragraphed for the convenience of students and others.

PART I. contains Sect. I. The Balance, Weights and Weighing. Sect. II. Specific Gravity, Melting Point, Boiling Point. Sect. III. Mechanical Division, Drying, Solution, Precipitation, &c. Sect. IV. Exercises on Crystallisation, &c. PART II. Simple Gravimetric Estimations. PART III. Volumetric Analysis, divided into four sections. PART IV. General Quantitative Analysis. Sect. I. Technical Analyses. Sect. II. Water Analysis. Sect. III. Food Analysis, Tannins, Soap. Under Food Analysis we have Milk Analysis, Butter Analysis, Partial Analysis of Beer and Wine, Analysis of Sugar, Partial Analysis of Tea. Sect. IV. Organic Analysis. PART V. Volumetric Estimations of Gases. APPENDIX, containing: I. Nitrate in Water; Preparation of Gases. II. Results of Typical Analyses. III. Tables of Useful Constants. IV. Lists of Apparatus and Chemicals Required.

THE ORGANIC ANALYSIS OF POTABLE WATERS. By J. A. BLAIR, M.B., D.Sc., Edin. Second Edition. London: J. and A. Churchill, 11, New Burlington Street. 1891.

SMALL 8vo. volume, bound in cloth, price 3s. 6d., containing Table of Contents, Preface to Second Edition, Introduction, and subject-matter covering 97 pages, and Appendices A. to E. The text up to the Appendices is divided into four parts. Part I. The Albuminoid-Ammonia Process, and Oxygen Process at ordinary temperatures. Part II. The Oxygen Process at 100° C. Part III. The Sulphuric Acid Process for Organic Nitrogen. Part IV. The Sulphuric Acid and Permanganate Process for Organic Carbon. The Appendices treat of the following subjects:—A. Solutions for Albuminoid Ammonia and Sulphuric Acid processes. B. Solutions for Oxygen Process at ordinary temperatures. C. Solutions for Oxygen Process at 100° C. D. Estimation of Nitrates by Arsenious Acid. E. Solutions for the Sulphuric Acid and Permanganate Process for Organic Carbon.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

RUSSIA.

The Duty on Starch.

Note.—Pound = 36 lbs. avoirdupois. Rouble = 3s. 2d.

The following is a copy of a memorandum which has been received from the Foreign Office on the subject of the duty on starch in the Russian tariff:—

Representations having been made with a view to obtain a reduction of the amount of duty, 1 r. 75 cop. per pound, on starch packed in paper or in cases, in the new Russian Customs tariff, the Russian Government has consented to allow cases of starch of not less than half a pound in weight to be imported at the lower rate of 1 r. 40 cop. per pound.

Regulations affecting Customs Declarations.

The *Journal des Tarifs et Traités de Commerce* for the 17th September says that, in consideration of the difficulties experienced by merchants in filling up declarations with detailed specification of certain merchandise, the Russian Minister of Finance has ordered that the declaration for the under-mentioned articles are admissible as stated, without other detailed indication:—

“Pyrites of iron, copper ores, and copper scoriae,” according to the notes 1 and 2 of Art. 138, without indication of the proportion of copper per pound.

“Cotton tissues, raw and bleached, dyed, coloured, and printed,” according to Arts. 187 and 188, without indication of the number of square arshines per pound of these tissues.

FINLAND.

Tariff Change.

Mr. J. Michell, Her Majesty's Consul at St. Petersburg, in a report to the Foreign Office, dated the 24th October, says that, according to an intimation from Mr. Vice-Consul C. J. Cooke, of Helsingfors, the Imperial Finnish Senate has decreed that half-made goods of aluminium shall henceforth pay a higher rate of duty, namely, the same as that charged under the Finnish tariff on copper and brass half-finished goods, which is 5 marks 90 pennis per 100 kilogrammes.

SWITZERLAND.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220·4 lb. avoirdupois. Franc = 9 $\frac{6}{10}$ d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities in the month of September last:—

Sulphate of barytes, washed, in paste.—Category 16. Duty, 30 cents. per quintal. This was formerly included in Category 30.

CHANGES IN THE CANADIAN CUSTOMS TARIFF.

By resolutions recently adopted by the Canadian House of Commons the following changes have been introduced into the Customs tariff of the Dominion. The old duties, published at pp. 409—18 of the October number, and pp. 535—52 of the November number of the *Board of*

Trade Journal for last year are modified on the under-mentioned articles:—

Articles.	Duties now levied.
All cane sugar and beetroot sugar not above No. 14 Dutch standard in colour, all sugar sweepings, all sugar drainings or pumpings drained in transit, all melado and concentrated melado, all molasses and concentrated molasses not elsewhere specified, all cane juice and concentrated cane juice not elsewhere specified, all beetroot juice and concentrated beetroot juice not elsewhere specified, all tank bottoms not elsewhere specified, and concrete when not imported direct without transshipment from the country of growth and production, 5 per cent. <i>ad val.</i> ; provided, however, that in the case of cane sugar produced in the East Indies and in countries to the east thereof and imported therefrom <i>via</i> Hong Kong or Yokohama, such rate of 5 per cent. <i>ad val.</i> shall not be exacted if transhipped at Hong Kong or Yokohama.	Dols. Cts. 5 00 <i>ad val.</i>
All sugars above No. 14 Dutch standard in colour, and refined sugar of all kinds, grades or standards, and all sugar syrups derived from refined sugars.	Lb. 0'00, 75
Glucose or grape sugar, glucose, syrup, and corn syrup, or any syrups containing any admixture thereof.	" 0'01 1/2
Spirituos or alcoholic liquors, distilled from any material or containing or compounded from or with distilled spirits of any kind, and any mixture thereof with water, for every gallon thereof of the strength of proof, and when of a greater strength than that of proof, at the same rate on the increased quantity that there would be if the liquors were reduced to the strength of proof. When the liquors are of a less strength than that of proof, the duty shall be at the rate herein provided, but computed on a reduced quantity of the liquors in proportion to the lesser degree of strength; provided, however, that no reduction in quantity shall be computed or made on any liquors below the strength of 15 per cent. under proof, but all such liquors shall be computed as of the strength of 15 per cent. under proof, as follows:—	
(a.) Ethyl alcohol, or the substance commonly known as alcohol hydrated oxide of ethyl or spirits of wine.	Gall. 2'12 1/2
(b.) Amyl alcohol or fusel oil, or any substance known as potato spirit or potato oil.	" 2'12 1/2
(c.) Methyl alcohol, wood alcohol, wood naphtha, pyrolytic spirit, or any substance known as wood spirit or methylated spirit.	" 2'12 1/2
(d.) Spirits and strong waters of any kind, mixed with any ingredient or ingredients, and being known or designated as anodynes, elixirs, essences, extracts, lotions, tinctures, or medicines not elsewhere specified.	Gall. 2'12 1/2 and 30 <i>ad val.</i>
(e.) Alcoholic perfumes and perfumed spirits, bay rum, cologne and lavender waters, hair, tooth, and skin washes, and other toilet preparations containing spirits of any kind, when in bottles or flasks weighing not more than 1 oz. each.	30 <i>ad val.</i>
When in bottles, flasks, or other packages, weighing more than 1 oz. each.	Gall. 2'12 1/2 and 30 <i>ad val.</i>
(f.) Nitrous ether, sweet spirits of nitre, and aromatic spirits of ammonia.	Gall. 2'12 1/2 and 30 <i>ad val.</i>

Note.—In all cases where the strength of any of the foregoing articles cannot be correctly ascertained by the direct application of the hydrometer, it shall be ascertained by the distillation of a sample, or in such other manner as the Minister of Customs directs.

GENERAL TRADE NOTES.

IRON AND STEEL PRODUCTION, 1890.

In an article which appeared in the *Viestnik Financoff* of October 4th were published particulars regarding the production of iron and steel in the seven principal iron-producing countries of the world, viz., the United States, the United Kingdom, German Empire with Luxemburg, France, Belgium, Austria-Hungary, and Sweden, which together produce 95 per cent. of the annual iron production of the world. The extent to which the production of pig iron has developed in each of these countries will be seen from the following table:—

	1870.	1880.	1890.
Production (in Tons of 2,204 lb.)			
United States.....	1,718,000	3,957,000	9,332,000
Great Britain.....	6,939,000	7,820,000	8,005,000
Germany*.....	1,170,000	2,763,000	4,696,000
France.....	921,000	1,727,000	1,963,000
Austria-Hungary.....	402,000	464,000	922,000
Sweden.....	202,000	404,000	820,000
Belgium.....	563,000	608,000	779,000
Total.....	11,105,000	17,743,000	26,517,000

* Excluding Lorraine and Luxemburg, where 3,400,000 tons and 3,300,000 tons of pig iron were respectively produced in 1890.

It will be seen from these figures that the iron industry of the United States shows a greater expansion than that of any of the other countries. The production of pig iron in the United States in 1890 was 21 per cent. greater than in 1889, which year showed an increase of 17 per cent. on 1888; it has doubled itself within the last six years, and increased threefold since 1878. On the other hand, it has taken Great Britain 27 years to double its production. The year 1890 was the first in which the production of pig iron in the United States exceeded that of Great Britain, not only for the same year, but for 1883, the year in which the pig iron production of the latter reached its maximum.

Germany, including Lorraine and Luxemburg, produced 11,400,000 tons of pig iron in 1890, almost exclusively from native ore. The total production of pig iron in Germany in 1889 was 11,000,000 tons. There were 2,469,000 tons of wrought iron, and 2,162,000 tons of steel produced in Germany in 1890, the corresponding figures for 1889 being respectively 2,769,000 tons and 2,095,000 tons.

In France, owing to the high rates of duty on coal and pig iron, the quantity of the latter produced in 1890 exceeded that of 1889 by 11 per cent., and France now produces all the iron and steel required for her own use, with the exception of a few special sorts still imported from England. The production of pig iron in France in 1890 and 1889 respectively was 1,900,000 tons and 1,700,000 tons, the quantities of wrought iron produced in the same years respectively being 823,000 tons and 793,000 tons, and of steel 566,000 tons and 529,000 tons.

Austria-Hungary produced, in round numbers, 920,000 tons and 850,000 tons of pig iron in 1890 and 1889 respectively. The corresponding figures for wrought iron being respectively 471,000 tons and 439,000 tons, and for steel 734,000 tons and 617,000 tons.

Hungary is recently attracting attention through the progress of her iron and steel industries, largely due to increased traffic on the railways, brought about by the zone system and causing a great increase in the demand for rolling stock, locomotives, tenders, and rails. Thus the average number of railway carriages built annually between 1880 and 1884 was 2,943, between 1885 and 1889, 3,462, while in 1890 the number built was 8,466.

Belgium contrasts with the other countries by a falling off in her production of pig iron and wrought iron, due to the high prices of coal and coke, and a fall in the price of the product itself. This unsatisfactory condition of the Belgian markets was to no small extent due to unfavourable competition with other countries. Belgian manufacturers in their endeavours to improve their position by reducing wages only made matters worse by bringing about strikes. There were 780,000 tons of pig iron produced in 1890 as compared with 830,000 tons in 1889; 507,000 tons of wrought iron as compared with 577,000 tons, and 455,000 tons of steel as compared with 469,000 tons.

As regards Sweden, owing to increased building and engineering activity both for home and abroad in 1890, the iron industry has made further progress. Large ship-building orders from Russia gave special impetus to that trade. Arms were manufactured for Switzerland and Denmark. There was a brisk demand for agricultural implements from Austria-Hungary and South America. The total production of steel in 1890 amounted to 160,026 tons, of which 92,247 tons were Bessemer steel. The total production of steel for 1889 was 135,227. The quantities of iron ore produced in 1889 and 1890 respectively were 787,950 tons and 823,334 tons.

PETROLEUM IN GALICIA.

A fresh discovery of petroleum is reported from Krusno in Galicia. Enormous masses of oil and water are forcing their way through the surface of the land, although at present the borings have not reached the oil-bearing strata proper. In the opinion of experts this striking of oil is the most important yet made in the district, the yield being already equal to 100 barrels a day.—*Ironmonger*.

GERMAN ZINC STATISTICS.

A German technical journal publishes some statistics showing the development of the zinc industry during the past ten years. Germany is the chief producer of this metal, her mines at present producing about 140,000 tons per annum, out of a total estimated output of 350,000 tons for the whole world. Curiously enough, although the development of the industry has made such rapid strides, the number of concerns engaged in it has diminished during the past 20 years, there being at present only 29 firms producing zinc, as against 35 in 1870. In 1881 the output in Germany was 105,500 tons, valued at 1,582,700*l*. In 1890 the make had risen to 139,270 tons, and the value to 3,059,900*l*. But whilst the augmentation of output has been advancing at the rate of about 8 per cent. per annum since 1885, the value of the metal is almost double what it was six years ago, in spite of periods of temporary weakness. The average selling price in 1881 for C.G.H. brand of Silesian zinc in Breslau was 30·83 m.; for W.H. and S.S. brands of Rhine zinc at Cologne, 32·66 m.; and for refined Galmaum and Blende in Frankfort a/M. 33·53 m. In 1890 these qualities fetched an average price at the several selling centres of 45 m., 47·92 m., and 47·02 m. respectively. The second largest zinc-producing country is Belgium, with about two-thirds, and the United States of America, with about one-half, that of Germany.—*Ibid*.

A PERMANGANATE OF POTASSIUM COMBINATION.

The formerly existing syndicate of German permanganate of potassium manufacturers came to an end about two years ago; since that time the makers have been underselling one another with great vigour. At last they seem to have become tired of that policy, for they now announce that, from 15th inst., they have placed the exclusive sale of their potassium permanganate in the hands of the Chemische Fabrik auf Actien (vorm. S. Schering) in Berlin. The two makers who have done so are Dr. M. Goldschmidt, of Cöpenick, and Gebr. Borchers, of Goslar. Messrs. A. M. Zimmermann will sell for the three firms (Scherings are also manufacturers of the article) in this country. We believe that at the present time there is only one other manufacturer in Germany, and his works are temporarily closed owing to removal.—*Chemist and Druggist*.

NEW MATERIAL FOR INSULATION.

A new material, known as litho-carbon, of which enormous deposits have been discovered in Texas, has been found to be an excellent insulator, having a resistance, it is claimed, seven times as great as any other known substance. The material is said to resist heat, salt air, water and gases of any kind, and is, therefore, well suited for paint. Under very high temperatures it softens, but will not burn. In its natural state this mineral is found in intimate mixture with white sand and sea shells, from which it can be separated by benzene as a black viscous material.—*Industries*.

PAPERS OF INTEREST TO TECHNOLOGISTS AND MANUFACTURERS.

The following articles in the *Board of Trade Journal* for November will repay perusal:—

The Patent Laws of Austria-Hungary	p. 521
The Coal Industry of India.....	p. 529
Coffee and Cocoa Production of Brazil.....	p. 534

THE OUTPUT OF BRITISH MINERALS.

There has recently been issued from the Home Office, a tabular return, showing the annual output of the principal minerals produced in the United Kingdom, from the year 1860 to the year 1890. The term United Kingdom includes the Isle of Man and Ireland. The quantity in tons, and the value in pounds, are given for each year. The compilations have been made from official returns by Mr. James B. Jordan, the Clerk of Mineral Statistics. Copies of the return may be obtained from Messrs. Eyre and Spottiswoode. For the benefit of our readers, the figures for last year (1890), are culled from the report:—

Mineral.	Quantity.	Value.
	Tons.	£
Alum clay (bauxite).....	11,527	5,763
Alum shale.....	6,420	802
Arsenic (white arsenic, crude and refined) produced from arsenical pyrites not included in the next line.	7,276	60,727
Arsenical pyrites	5,114	4,414
Barytes.....	25,353	29,684
Clays (china clay, potters' clay, fullers' earth, &c., but exclusive of ordinary clays)	3,308,214	899,166
Coal	181,614,288	74,953,997
Cobalt and nickel ore	84	260
Copper ore and copper precipitate:—		
Copper ore	12,136	27,801
Precipitate	345	4,670
Fluorspar	268	392
Gold ore (auriferous quartz).....	575	434
Gypsum.....	140,293	57,991
Iron ore	13,780,767	3,926,145
Iron pyrites.....	16,018	7,666
Lead ore	45,351	406,164
Manganese ore	12,444	6,733
Ochre and umber.....	19,068	17,475
Oil shale.....	2,212,250	608,369
Phosphate of lime	18,000	29,500
Salt (rock salt and salt obtained from brine)	2,146,349	1,100,014
Slates and slabs.....	434,352	1,027,235
Sulphate of strontia	10,276	5,138
Tin ore ("black tin").....	14,911	782,492
Wolfram	104	1,848
Zinc ore	22,041	109,890

It is to be noted that, in addition to the above, small quantities of other minerals are occasionally produced, e.g., ores of antimony and bismuth, bog-iron ore (used for purifying gas), jet, lignite, petroleum, plumbago, silver ore, steatite, and uranium ore.

"A very large quantity of stone used for building and other purposes is also annually raised, besides chalk, ordinary clay, gravel, &c., the total quantity of which cannot be accurately ascertained, but the value in 1890 was estimated to be upwards of 8,708,000*l*."—*Chemical Trade Journal*.

THE USE OF METRIC WEIGHTS AND MEASURES IN EXPORT TRADE.

The *Engineering and Mining Journal* has already called the attention of certain American manufacturers, engaged in the export trade, to the universal employment of metric weights and measures in South American countries, whose markets the United States is now endeavouring to control, and the pressing importance of furnishing to them machinery of metrical gauges and dimensions. That journal now goes on to say that it is evident that to secure a commanding position in the trade of any of these countries there must be a strict compliance with local customs and demands. That this has not been done has been the burden of the complaints of American consular officers at foreign ports for many a year. The necessity in this particular point—metric weights and measures—is, however, so obvious that it should impress itself upon American manufacturers.

Appropos of this subject several recent reports of British consular officers are of service. British consuls in countries as widely separated as Italy and Japan have thus warned the manufacturers and exporters of their own country that they were losing trade because they persisted in using, in their circulars and price lists, English weights and measures, which were almost unintelligible to the people of these countries, where the metric units are in general use; whereas their French and German competitors, the former as a matter of course and the latter adapting themselves to the circumstances with the facility which has gained them such an immense export trade to all parts of the world, employ the metric system, which is familiar to everybody, and naturally attract custom. Similar warnings are uttered by the British consuls at Alexandria and Cairo, in Egypt, who declare that British manufacturers are simply playing into the hands of their rivals by continuing the use of weights and measures which to many Egyptian merchants are no more intelligible than those of China.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

SPAIN.

Decline in the British Drug Trade.

The British Consul at Bilbao is very pessimistic about the decline in several important branches of commerce with Spain, in which this country formerly took the lead. Drugs is one. The following significant figures are given:—

Imports from.	1883.	1884.	1885.	1887.	1888.	1889.
	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.
United Kingdom . . .	896	852	744	210	170	165
Other countries	41	111	237	202	1,363	1,807
Total	937	963	981	412	1,533	1,972
British percentage . .	95.56	88.47	75.86	50.98	26.51	8.35

The three years 1883—85 illustrate the condition of things previous to the Anglo-Spanish convention of 1886—a con-

vention which was believed to be particularly favourable to British trade—and the triennium 1887—89 the state of business subsequent to the convention.

Its Causes.

With regard to other staple articles, it may be observed that in the British imports of woollens, mineral oils, paraffin, paints and dyes, and varnishes, there was a fair increase during the years succeeding the convention, while copper and brass, glass, porcelain, and agricultural and industrial machinery show a large decrease. The result cannot be regarded as satisfactory.

Bearing in mind (continues the Consul) that the general commerce of Bilbao has considerably advanced, it might have been anticipated that Great Britain would have absorbed a larger share of the trade in those articles in which, previously to the convention, she was unfairly handicapped with other foreign countries. Under the heads of drugs and chemicals the figures are so discouraging that some explanation seems called for. Since many years France, Germany, and Belgium have made strenuous efforts to secure the command of the trade of Bilbao, and on the convention with Great Britain being concluded, those efforts were redoubled, while the British trader, unmindful of the advice so often given him, has not changed his way of doing business. He does not take the proper steps to further a demand for his goods by offering the same facilities as French, German, and Belgian traders, such as employing active and intelligent agents acquainted with the language of the country, the manners and customs of the people, the tastes and requirements of particular districts, and empowered to make sales, contracts, and financial arrangements in accordance with the usage of respective places, without delay or reference to the houses they represent. With respect to financial accommodation, it would appear that the British trader is indisposed to conform to the custom and views of Spanish buyers, and while he follows the prudent course of requiring cash payments or short bills for his consignments, his competitors offer every facility in the shape of long credit; thus, although it is notorious that, were the conditions of business the same, preference would in many cases be given to British produce and manufactures, our traders are constantly driven out of the market on this ground. In a word, it cannot be again too seriously urged for the consideration of British traders that until they adopt a system similar to that of their keen opponents, they must not expect to be otherwise than at a disadvantage.

New Industries.

Several new industries were initiated in Bilbao last year, among them a chemical factory, established by Messrs. Burt, Boulton, and Haywood, of London, for the treatment of coal tar and extraction of various products, including aniline and other colours.—*Chemist and Druggist*.

FOURTEENTH MEETING OF THE SOCIETY FOR PROTECTING THE INTERESTS OF THE GERMAN CHEMICAL INDUSTRIES.

This meeting took place on September 19th at Nuremberg, under the presidency of Dr. J. F. Holtz. In presenting the annual report, the secretary, Mr. O. Wenzel, stated that the progress of the last five years still continued and factories had been fully employed, although prices, owing to keen competition, had in many instances hardly kept pace with the great increase in cost of production. The number of works had increased from 4,809 to 5,043 during the year, employes from 90,585 to 97,198, or 7.63 per cent., and wages from 3,580,552*l*. to 4,003,735*l*. The foreign trade amounted in 1890 to 1,916,522 tons, valued at 26,828,300*l*., or an increase over the preceding year of 40,275 tons, valued at 495,600*l*.

The following table supplies the necessary details:—

	Imports.		Exports.	
	Raw Materials.	Manufactured Products.	Raw Materials.	Manufactured Products.
Tons.....	Tons. 1,916,254	Tons. 219,915	Tons. 257,126	Tons. 422,927
Increase	10,169	28,046	..	10,261
Decrease	17,204	..
Value.....	£ 7,496,300	£ 5,506,800	£ 1,629,100	£ 12,105,500
Increase	265,800	8,250	766,200
Decrease	514,950

It will be seen that whilst the value per ton in the case of the imports had declined from 11*l.* 3*s.* 4*d.* to 10*l.* 11*s.* 10*d.*, the corresponding figures for the export trade show a rise from 19*l.* 2*s.* to 20*l.* 3*s.* 9*d.* per ton, or about 5 per cent.

This rise is explained by the increased proportion of goods of a higher value, and not by an increase in price, as might be assumed at first sight. The increase in the cost of production, on the other hand, is estimated at about 3½ per cent., chiefly owing to higher wages and larger coal bills. Any prosperity in the chemical industries must, therefore, have resulted not from higher prices having been obtained in the market, but from the increase in the volume of trade. The published accounts for 1890 of 82 limited companies show a capital of 9,903,655*l.*, on which was divided 1,269,465*l.* or an average of 12·81 per cent.

The following figures show the proportionate earnings of these 82 companies:—

Eighteen companies, or 22 per cent. of the whole, paid no dividend.

Two, or 2½ per cent., paid from 0 to 2½ per cent.

Fifteen, or 18 per cent., paid from 2½ to 5 per cent.

Five, or 6 per cent., paid from 5 to 7½ per cent.

Fifteen, or 18 per cent., paid from 7½ to 10 per cent.

Fourteen, or 17 per cent., paid from 10 to 15 per cent.

Thirteen, or 16 per cent., paid over 15 per cent.

The average dividends for the previous years amounted to:—

	Per Cent.
1882	12·82
1883	10·02
1884	7·96
1885	6·37
1886	7·17
1887	8·92
1888	9·78
1889	10·58

so that since 1885 there has been a steady improvement. The earnings of the *Alkali Companies* for 1890 (including the same companies during the last five years) are as follows:—

	Per Cent.
1886	4·61
1887	5·34
1888	5·97
1889	6·87
1890	7·18

so that in this important industry there is also a decided improvement. The *Stassfurt salt industries* details did not, however, share in this improvement, while the *potassium industry* remained substantially unaltered. The demand for saltpetre suffered from the introduction of smokeless powder, and the same was the case with potassium chlorate. Potassium bichromate had a hard struggle against English competition. After a long period of depression the *soda industry* has improved, partly due to the formation of the United Alkali Company. Whereas formerly imports of soda exceeded exports by 28,000 tons, the position is now reversed, and the excess of exports almost amounts to the figure quoted.

This is considered to be due to the Customs tariff which has strengthened home production without affecting consumption.

Pharmaceutical, Photographic, and other Technical Chemicals yielded an average dividend of 11·10 per cent. In the interests of this branch a possible increase in the Italian tariff is much to be deprecated, as tending to close a portion of the foreign market. Ether and alcoholic preparations have been gravely affected owing to the anomalies in the Customs tariff. Movements have been set on foot to remedy this evil, and the various Governments have been petitioned. Mineral colours have been in great demand at home, although business has not been easy in foreign markets, partly through Customs tariffs and partly through competition. With England and Belgium, however, the trade has been good. The syndication of the ultramarine factories has done much good, and the prospects of this industry are considered good. Agitation for syndicating the *Soap* manufacture has not yet had any result. The *Coal-Tar Colour Industry* is satisfactory, and the large factories divided an average of 20·75 per cent., previous years showing the following figures:—

	Per Cent.
1886	20·94
1887	13·25
1888	15·44
1889	17·50

Attention is drawn to the still growing importance of coal-tar colours, to which are attributable in a large measure the good results obtained.

The trade in *Explosives* has likewise been successful, average dividends being as high as 18·88 per cent., the figures for the previous years being:—

	Per Cent.
1886	16·09
1887	14·08
1888	15·41
1889	15·90

Last year's good results are mainly due to the older dynamite exporters, among whom there exists a syndicate which has done much to assist business. Gunpowder for exportation has done well, partly owing to orders from Africa, partly owing to the growing favour in which German makes are held in foreign markets. 1890 marked a great change with respect to gunpowder for military purposes, but it is pretty clear that the old makes of powder will hold their own for a long time to come, particularly as regards guns of large calibre. The *Gun-cotton, Detonator, and Match trades* have not shown any remarkable features, the former in fact not having been very flourishing.

Artificial Manures have earned an average dividend of 10·21 per cent. clearly showing that the importance of these products is being more and more recognised every year. In spite of determined competition from England it is said that German manufacturers continued to hold the field owing to greater care in selection of raw materials and mechanical preparation, the main object being to produce superphosphate as dry and finely ground as possible. Arrangements have been made with the agricultural experimental stations ("Versuchsstationen") with a view to guaranteeing to consumers the supply of certain brands. The extended use of *Thomas slag* appears to have benefited the superphosphate industry rather than proved detrimental to it as had been feared.

The Secretary, after alluding to a proposed alteration in the Society's subscription and certain contemplated improvements and extensions of the Society's Journal, went on to say that the new German patent law would afford increased protection to inventors, particularly in the chemical world; and it was matter for congratulation, he thought, that the Society's exertions in this direction had been so successful. The researches of the Society into the results of the McKinley tariff, as far as the German chemical industries were concerned, had not shown so far any direct injury, but certain branches of the trade had certainly suffered indirectly through slackness in the demand for certain chemicals required in the textile trade.

Dr. Martins then referred to the participation of the chemical industries in the Chicago Exhibition, 1893. The members had already expressed their readiness to take part in the exhibition, but he thought that the Imperial Government should assist with funds in order to ensure as complete a representation as was possible. He estimated that about 300,000*l.* would be required, a portion to be expended in assisting exhibitors in the cost of transport, but the bulk for the artistic decoration of the buildings and exhibits. The Paris Exhibition showed the immense advantage reaped by French exhibitors from their skill in displaying their goods in an imposingly decorative manner, and he thought that preparations in this direction could not be commenced at too early a date. *Herr Caspar*, taking up the discussion, agreed with the last speaker in regard to his main point, but thought the sum named was unnecessarily large. The Prussian and Bavarian State railways had already expressed their willingness to carry exhibition goods at one-half of the ordinary rates, and negotiations were pending with the steamship companies with a view to securing a similar concession. From all reports to hand, he imagined that the competition from other countries would be very keen. *Dr. Witte* spoke in corroboration, and the motion of *Dr. Martins* to appoint a special committee to open a list for applications from intending exhibitors was unanimously approved.

Herr Siegel reported on the exceptions to the prohibition of Sunday labour, and, after a discussion, it was agreed that a sheet of queries should be forwarded to every member, in order to get the information necessary for submitting proposals to the Federal Council. A motion was then carried, brought forward by *Dr. Hecht*, to petition the Government on the subject of the protection of factory and business secrets. Further motions referred to "concessions of industrial establishments" (moved by *Herr Kaupp*), "the carrying into effect of patents in foreign countries" (*Herr Baettinger*), and "the use of duty-free alcohol for industrial purposes" (*Dr. Witte*). (Compare this Journal, 1890, 1080—1082.)—H. S.

Total value	792,673	798,180

Monthly Patent List.

*The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

17,886. H. H. Lake.—From La Société Anonyme du Compresseur Jourdan, France. Improvements in and relating to apparatus for expressing liquids from vegetable, animal, or mineral substances. October 19.

18,000. T. Spendlove. Improvements in apparatus for raising fluids, semi-fluids, and pulverulent substances. October 20.

18,008. A. Allen. Improvements in evaporating pans. October 21.

18,042. W. Muirhead and J. Macfarlane. *See* Class X.

18,084. J. H. Frazer. Improvements connected with furnaces. October 21.

18,113. C. L. Clarke and J. Leigh. Improved apparatus for evaporating and cooling liquids. October 22.

18,116. W. Birch. Improved apparatus for mixing powdered substances with water or other liquids. October 22.

18,216. S. Smithson. Improvements in or relating to means or apparatus for drying dyewoods, myrabolon grain, fuller's earth, night soil, and other pulpy matter. Complete Specification. October 23.

18,483. T. Phipps. An improved stop valve for liquids, vapours, or gases. Complete Specification. October 27.

18,488. J. Sutton. *See* Class XVII.

18,533. J. Wright. Improvements in the construction of vertical stills for the distillation of ammoniacal and other liquors or liquids. October 28.

18,550. R. C. Sayer. Improvements in gaseous pressure apparatus. October 28.

18,876. W. R. Dunstan and T. S. Dymond. An apparatus for shaking, mixing, and generally for purposes of agitation. November 2.

18,904. E. Hesketh and O. J. Ellis. An improvement connected with the employment of carbonic acid gas in refrigerating apparatus. Complete Specification. November 2.

18,959. A. Feldmann. Improvements in distilling apparatus suitable for the treatment of ammoniacal liquors. November 3.

19,027. H. S. Fearon and W. S. Miller. A new or improved process for desiccation or evaporation. November 4.

19,042. H. H. Partridge and J. Millward. Improvements in apparatus for compressing air or other gas by hydraulic pressure. November 4.

19,335. L. Sterne and T. R. Murray. Improvements in regulating apparatus for refrigerating or freezing machines working with volatile liquids. November 9.

19,464. E. Kerr. Improvements in furnaces. Complete Specification. November 10.

19,475. A. Backus, jun. Improvements in furnaces. Complete Specification. November 10.

19,486. D. B. Morison. Improvements in and connected with apparatus for heating or evaporating liquids. November 10.

19,607. H. A. A. Dombrain. Improvements in apparatus for squeezing liquids from pulverulent and granular substances. November 12.

19,780. C. J. Schofield. *See* Class VII.

COMPLETE SPECIFICATIONS ACCEPTED.*

1890.

19,071. O. Murray.—From A. Bergh. Method and apparatus for subjecting liquids having substances suspended in them to centrifugal action, whereby they are brought into contact only with sterilised or with other air, with which they are to be saturated. November 18.

19,550. J. Kirkaddy. Apparatus for heating and evaporating liquids. November 4.

20,831. F. C. Nunn. Apparatus for purifying water. October 28.

20,951. J. A. Drakenberg. Mode of and apparatus for separating fat, grease, or other impurities from the feed-water of steam boilers and other water. October 28.

20,955. O. Clausen. Manufacture of porous magnesian bricks for the linings of stoves, furnaces, fire-places, and flues, and the construction of stoves and furnaces with such bricks. November 4.

1891.

101. W. H. Wilcox. Filter for oils, lubricants, and other fluids. November 11.

16,248. T. Ledward. Improvements in or relating to open air fluid condensers. November 11.

17,034. H. C. Cox. Apparatus for the automatic control of sulphuric acid supply to carbonic acid generators used in aerated water manufacture and other industries. November 11.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

18,082. The Gas Economising and Improved Light Syndicate, Limited, and J. Love. Improvements in apparatus for carburetting gas or air. October 21.

18,094. J. Major. An improved method for utilising gas. October 21.

18,158. T. McGhie. Improvements in or connected with retorts for the distillation of mineral oil. October 22.

18,213. J. W. Harrison, T. Hammond, and W. Powell. Improvements in the method of and means employed in charging gas retorts. October 23.

18,377. A. Johnson and The Co-operative Inventive Association, Limited. Improvements in the method of removing naphthalene from the inlet pipes of gas holders. October 26.

18,409. G. T. J. Webb. Improved method of producing oxygen gas for illuminating purposes. October 26.

18,414. R. Campion and T. W. Butler. The manufacture of fire-lighters and artificial fuel from a waste material. October 26.

18,498. H. H. Lake.—From C. H. Wilder, United States. Improvements relating to the manufacture of gas from hydrocarbon oils, and to apparatus therefor. Complete Specification. October 27.

18,608. J. C. Chandler and W. Sims. Improvements in apparatus for purifying gas. October 28.

19,152. C. Winter. Winter's improved compound fuel. November 6.

19,235. G. Wilton. Improvements in and relating to the purification of coal-gas, and the recovery of products from the distillation of coal. November 7.

19,418. J. G. Cooper. Improvements in the treatment of petroleum. Complete Specification. November 10.

19,496. J. Lyle. The treatment of ingredients for the manufacture of fuel briquettes. November 10.

19,641. T. G. Springer. Improvements in the manufacture of gas, and in apparatus to be used therein. Complete Specification. November 12.

19,758. Sir G. Elliot, Bart., and J. MacGowan, jun. Improvements in or relating to the manufacture of coke. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,618. T. A. Greene and C. M. Walker. Improvements in gas lighting. November 18.

18,871. H. Williams. Method and apparatus for burning gas for heating and steam generating purposes. October 28.

18,872. H. Williams. Improvements in gas generating apparatus. October 28.

19,963. A. Vinard. Producing and supplying gas for lighting and motive power, and apparatus therefor. October 28.

1891.

23, J. O. Spong. Improved arrangement of apparatus for obtaining chromatic illumination from gas or other flame. November 11.

13,179. D. C. Fischel. Improvements in artificial fuel. October 28.

16,907. L. T. Wilcox. Devices for heating and lighting. November 18.

17,557. A. Kitson. Apparatus for manufacturing gas. November 18.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

APPLICATIONS.

19,255. G. Wilton. *See* Class H.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

19,502. A. M. Clark.—From The Gewerkschaft Messel. Production from mineral oils of sulphonic acids and sulphones, and the manufacture of a new product for treating gelatinous matters with sulphonic acid. October 28.

1891.

17,221. E. Binney. *See* Class XIII.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

18,606. H. H. Lake.—From Messrs. Wirth and Co., agents for A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. October 28.

18,783. O. Inray.—From The Farbwerke vormals Meister, Lucius, and Brünig, Germany. A new manufacture of colouring matter. October 31.

19,061. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of new cotton or substantive dyestuffs. November 4.

19,062. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in or connected with the manufacture and production of colouring matters. November 4.

19,096. R. Hunt, E. S. Wilson, and E. Stewart. Improvements in the manufacture of colouring matters. November 5.

19,097. R. Hunt, E. S. Wilson, and E. Stewart. *See* Class XII.

19,202. W. J. J. Hawkins. Improvements in copying ink. November 6.

19,588. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of new blue mordant dyeing colouring matters. November 12.

19,589. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of new blue mordant dyeing colouring matters. November 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

20,889. O. Inray.—From The Farbwerke vormals Meister, Lucius, and Brünig. Production of azo-colouring matters. October 28.

21,284. J. R. Greig. Manufacture of diethyldibenzyl-diamidodiphenylmethan-disulpho acid and violet dyestuffs therefrom. October 28.

1891.

857. S. Pitt.—From L. Cassella and Co. Improvements in triphenylmethane colouring matters. November 18.

1737. O. Inray.—From the Actien Gessellschaft für Aniline Fabrikation. Manufacture of colouring matters. November 11.

1883. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of new dyestuffs derived from anthracene and anthraquinone. November 18.

V.—TEXTILES, COTTON, WOOL, SILK, ETC.

APPLICATIONS.

18,129. J. Miller, sen., and J. Miller, jun. Improvements in the method of and apparatus for rendering textile fabrics waterproof by one treatment or process. October 22.

18,389. G. Mort. Improvements in the manufacture of figured textile fabrics. October 26.

18,470. C. G. Hagemann. Manufacture or production of cellular substance and textile fibre. October 27.

18,851. W. Golding. An improved compound of india-rubber and fibre formed by treating fibrous fabrics, yarns, cords, &c., with rubber, so that the fibrous material is permeated by the rubber, and the individual fibres are embedded therein, constituting a new manufacture to be called "Rubric," and processes, apparatus, and machinery for producing the same. October 31.

18,878. S. Fisher and H. Murgatroyd. Improvements in machinery or apparatus for cleaning and lustring dyed or undyed yarns of silk, cotton or other fibrous substances. November 2.

19,135. L. E. Vial. Improved means applicable for use in the treatment of China-grass, and other plants adapted for employment in the textile industry. Complete Specification. November 5.

19,710. F. G. Annison. Improvements in the treatment of linen and other textile fabrics, applicable to the manufacture of show bills, show cards, posters, tablets, wall decorations, and other purposes. November 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

20,257. A. H. Briggs. Method and apparatus for scouring, drying, and stretching mohair, alpaca, and such like wools and yarns. October 28.

20,267. A. Ambler, S. Ambler, and F. Ambler. Improvements in the cleansing, treating, washing wool and like animal fibres, and in apparatus employed therein. November 18.

20,806. J. Longmore and R. Williamson. Improvements in the combing of rhea and similar inelastic fibres. November 1.

1891.

92. C. W. Kimmis and T. Craig. See Class XII.

19,644. R. Ingham. Improved compound or mixture for use in sizing yarn and fabrics. November 4.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

17,887. F. Odenheimer. Process for printing and dyeing textiles, fibres, hair, feathers, and the like by means of metal salts. Complete Specification. October 19.

17,939. J. Smith. Improvements in or connected with dyeing, tinting, sizing and bleaching, or similarly operating upon textile fabrics or fibres, and other materials. October 20.

18,167. E. C. Kayser. Improvements in dyeing and printing textile fibres, fabrics, and like materials. October 27.

18,588. G. Young and W. Crippin. Improvements in the construction of hollow perforated skewers employed for dyeing and otherwise treating cops of yarn or thread, and in their arrangement in connection with the parts on which they are to be used. October 28.

18,809. E. C. Kayser. Improvements in dyeing or colouring textile fibres and fabrics. October 31.

18,848. R. E. Flynn. Improvements in the manufacture of linoleum floor-cloth. October 31.

18,879. G. McConnell. An improved waterproofing solution, chiefly applicable in the staining of paper. November 2.

19,113. W. Ward. Improvements in colouring cork used in the manufacture of floor coverings, and in apparatus used in colouring the same. November 5.

19,342. J. Kennedy. Improved composition or compound to be used in bleaching cotton, linen, or woollen fabrics. November 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

17,694. E. W. Foxlee. Printing with prinauline. November 11.

21,062. C. E. Maistre and J. M. Compagnie. Dyeing of textile fabrics or materials with indigo, and the manufacture of saponaceous matter employed therein; also applicable for other operations in which saponaceous material is required. November 4.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

17,911. H. C. Saeré and H. Grimshaw. The utilisation of the waste oxide of iron produced in the manufacture and purification of chloride of zinc. October 20.

17,933. W. P. Thompson.—From J. A. Bradburn and J. D. Pennock, United States. Improvements in the manufacture of alumina. Complete Specification. October 20.

18,066. H. Kohler. Improved method for the manufacture of picric acid. October 21.

18,159. A. Vogt. Improvements in the treatment of nitrate of alkalis for the manufacture of nitric acid and its by-products. October 22.

18,231. D. Rylands. Improvements in means or processes for producing carbonic acid gas. October 23.

18,324. L. Brunner and A. Zauner. An improved process for manufacturing nitrate of ammonia or chloride of ammonia, simultaneously obtaining either precipitated phosphate of lime or an enriched phosphate of lime. Complete Specification. October 24.

18,481. J. E. Bott. Improvements in the manufacture of salt. October 27.

18,482. J. E. Bott. Improvements in the manufacture of caustic alkalis. October 27.

18,548. J. Simpson. Improvements in the manufacture of carbonated alkali and caustic soda. October 28.

18,693. W. Smith. See Class XIII.

18,700. C. W. Vincent. Improvements in the preparation of mineral salts for bathing and drinking purposes. October 29.

18,861. A. McDougall. Improvements in the manufacture of nitrate of ammonia. November 2.

18,959. A. Feldmann. See Class I.

19,016. T. H. Williams and W. H. Symons. Improvements in the manufacture of carbonic acid gas. November 4.

19,051. O. Wolff and R. Chug. Improvements in or connected with the manufacture of soluble silicates. November 4.

19,207. H. W. Wallis. Improvements in the manufacture of caustic alkalis. November 6.

19,215. J. L. Kessler. Improvements in and apparatus for the concentration of sulphuric acid. November 6.

19,342. J. Kennedy. Improved composition or compound to be used in bleaching cotton, linen, or woollen fabrics. November 9.

19,375. C. Hoepfner. Improvements in and relating to the manufacture of chlorine. November 9.

19,382. C. Bigot and J. Schreiter. Improvements in the manufacture of sodium borates. Complete Specification. November 9.

19,453. A. J. Boulton.—From C. E. Ongley and O. D. Ballert, United States. Improvements in the preparation of salt. Complete Specification. November 10.

19,637. E. Edwards.—From H. Bauer and J. Syiketta, Germany. A new or improved process for the production of boron sulphate compounds, and the application of such products to the unliming of hides or skins, and to prevention of putrefaction. November 12.

19,780. C. J. Schotfield. Improvements in apparatus for concentrating sulphuric and other acids. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

19,776. J. Simpson. Improvements in the manufacture of chlorine. November 4.

21,225. F. M. Lyte and O. J. Steinhart. Production of chlorine and of strong hydrochloric acid. November 11.

1891.

5352. F. M. Lyte. Production of alkaline carbonates and chlorine and their derivatives. October 28.

15,288. R. J. Brice. A process of utilising galvaniser's waste. November 18.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

18,189. E. Edwards.—From K. Goetz, Germany. Improvements in the liquid material or "slip" used in the manufacture of porcelain, stoneware, and the like. Complete Specification. October 22.

18,230. D. Rylands. Improvements applicable to furnaces or retorts used in the production of glass and for similar purposes. October 23.

18,281. C. D. d'Enghien, A. D. d'Enghien, and S. D. d'Enghien. Improvements in kilns or ovens for firing terra-cotta and other like materials. Complete Specification. October 24.

18,559. T. Arnold. Improvements in the utilisation of slag for the manufacture of blocks, slabs, drain pipes, or other moulded articles. October 28.

18,939. J. W. Bonta. Method of and apparatus for rolling plate or sheet glass. Complete Specification. November 3.

19,441. W. W. Pilkington. Improvements in apparatus for forming molten glass into sheets. November 10.

19,527. T. Willett. Improvements in automatic machinery for the manufacture of pottery. November 11.

19,777. T. C. J. Thomas. Improvements in the construction of tank furnaces for the manufacture of glass. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

17,407. T. G. Webb. Improvements in the manufacture of glass retorts as used in chemical works for the concentration of acids, and other analogous purposes. November 4.

20,857. G. Swift. Improvements in tiles, fence ware, and other fictile ware required to be cemented to plane or other surfaces. October 28.

20,955. O. Clausen. A manufacture of porous magnesian bricks for the linings of stoves, furnaces, fire-places, and flues, and the construction of stoves and furnaces with such bricks. November 4.

21,212. J. B. Alzugaray. Manufacture of refractory materials or articles. November 18.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

18,284. W. A. Briggs. An improved marine cement. October 24.

19,106. D. Ward. Making coloured stucco, coloured concrete blocks, and tiles. November 5.

19,467. J. C. Bloomfield. Improvements in the manufacture of plaster. November 10.

19,534. W. Briggs. An improved concrete paving or flooring. November 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,603. T. Arnold. Improvements relating to the manufacture of cement, and the means employed therefor. October 28.

18,922. W. Smartt. Process of drying or burning bricks, pipes, tiles, and other goods in clamps, kilns, and other works, and in apparatus for effecting the same. October 28.

1891.

17,466. T. A. Lee. Improvements in fireproof floors and roofs. November 18.

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

17,851. G. W. Hart. A process and apparatus for deoxidising or reducing metallic oxides. October 19.

17,933. W. P. Thompson.—From J. A. Bradburn and J. D. Pennock, United States. See Class VII.

17,955. C. W. Pinkney. An improved metallic alloy, more especially intended for use for gas or petroleum engine igniters or like articles subjected to great heat. October 20.

18,042. W. Muirhead and J. Macfarlane. Improvements connected with steel-melting and other gas-fired furnaces. October 21.

18,069. J. B. Alzugaray. Improvements in iron or steel alloys. October 21.

18,442. W. A. Sugden.—From W. R. Sugden, United States. Improvements in the manufacture of iron, and in fuel or a compound suitable therefor. October 27.

18,501. J. Nicholas. Improved means of extracting precious metals from their ores. October 27.

18,559. T. Arnold. See Class VIII.

18,752. J. A. Norton and J. Noad. Improvements in or relating to means used in effecting the extraction of precious metals from their ores and other compounds. October 30.

18,850. J. M. McMahan. Improvements relating to the extraction of precious metals from their ores, and to apparatus therefor. October 31.

18,907. J. M. McMahan. Improvements relating to the extraction of precious metals from their ores, and to apparatus therefor. November 2.

18,990. J. Colley. Improvements in adding metallic and non-metallic substances to steel and iron. November 4.

19,118. H. Le Neve Foster. Improvements in the manufacture of iron. November 5.

19,191. F. W. Martino. Improvements in the manufacture of alloys of nickel and copper, and of alloys of nickel and iron, and of alloys of nickel, copper, and iron. November 6.

19,254. C. J. L. Lefler. Improved alloys for the manufacture of cutting tools. November 7.

19,330. J. Johnson.—From J. Gayley, United States. Improvements in blast furnace linings. November 9.

19,389. S. H. Johnson and C. C. Hutchinson. Improvements in leaching ores and in apparatus therefor. November 10.

19,457. J. L. Hopper. Improvements in furnaces for roasting, smelting, and separating refractory and other ores. Complete Specification. November 10.

19,501. R. Woodley, J. Spear, and W. Harris. A process for solidifying steel, iron, or other material susceptible to magnetic influence by the application of electrical energy. November 11.

19,563. A. I. Gravier, A. Schanschieff, and K. Sando. Improvements in hardening and tempering steel and other metals. November 11.

19,573. G. Selve. A process of separating cobalt from nickel. November 11.

19,599. A. Fairley and J. F. Fairley. Improvements in the manufacture of hollow ingots or other hollow castings from steel or ingot iron. November 12.

19,771. A. K. Huntington and J. T. Prestige, jun. An improvement in copper alloys. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

17,380. J. von Langer and L. Cooper. Improvements in or connected with reverberatory furnaces for puddling or smelting iron, and for other purposes. October 28.

18,080. C. Hopfner. Improved method of treating cupreous liquors for the purpose of utilising the same. November 11.

18,869. A. Gutensohn. Improved method of and process for annealing metal plates and sheets, and apparatus for use in the same, and for other purposes. October 28.

18,869. A. Gutensohn. Apparatus for preparing metal plates and sheets for annealing and for coating with tin or other metal. October 28.

18,934. W. Paterson and R. Stark. Extraction of metals from ore. October 28.

20,588. R. Martin and R. Evans. Means or apparatus employed in pressing or consolidating quantities of scrap metal. October 28.

20,768. G. J. Atkins and E. Applegarth. Means and apparatus for separating alkaline and earthy metals, and other products from the salts of such metals, or from other substances containing them. October 28.

20,895. J. E. Bott. Manufacture of armour plates and other similar articles. October 28.

21,025. L. Mond. New or improved manufacture of articles of nickel, and of nickel plated goods. October 28.

21,234. E. A. Bath. Utilisation of refuse or scoria of copper-smelting furnaces as a grinding or polishing agent or as a substitute for emery. November 4.

1891.

165. A. Sailer. Manufacture or production of metal plates hardened at one side. November 11.

205. C. Cochrane. Improvement in blast furnaces. November 18.

1785. L. Meyer. Production of aluminium. October 28.

11,337. C. James. An improved method or process for the collection of refined copper. November 4.

11,791. I. Edwards. From L. Pszeolka. Process for the manufacture of compound armour plates and armour-plated turrets. October 28.

15,288. R. J. Brice. See Class VII.

16,192. E. Edwards. From H. Shoenwacker. Improvements in Siemens-Martin furnaces. October 28.

16,486. L. L. Bordon. Manufacture of seamless compound ingots and wire. November 11.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY

APPLICATIONS.

17,994. R. Schenbauer. Improvements in and relating to electric batteries. Complete Specification. October 20.

18,097. C. N. Souther. Improvements in galvanic batteries. Complete Specification. Filed October 22. Date applied for March 23, 1891, being date of application in United States.

18,143. H. A. Mavor, W. A. Coulson, and S. Mavor. Improvements in the method of mounting storage battery plates. October 22.

18,256. A. S. Ford. From H. Pottier, France. An improved process for the electro-deposition of metal upon the surface of glass, porcelain, china, earthenware, and other materials. October 23.

18,431. M. Waddell, J. B. Entz, and W. A. Phillips. Improvements in secondary batteries. Complete Specification. October 27.

18,477. O. Schlesinger. A depolarising liquid for galvanic batteries. October 27.

18,522. W. P. Thompson. From C. L. Coffin, United States. Improved method of and apparatus for welding or working metals electrically. October 27.

18,597. E. Andreoli. Improvements in electrolysis. Complete Specification. October 28.

18,626. J. C. Richardson. Improvements in the construction of electrodes for use in the electrolysis of solutions. October 29.

18,627. J. C. Richardson. Improvements relating to electrodes to be used in the electrolysis of solutions. October 29.

18,931. J. Pullman and H. Lane. Improvements in apparatus and process for obtaining aluminium or other metals by means of electricity. November 3.

18,974. T. Parker. Improvements in electric furnaces for the manufacture of phosphorus or other matters capable of being volatilised by heat. November 3.

19,458. W. P. Thompson. From N. H. Edgerton, United States. Improvements in electric accumulators or storage batteries. Complete Specification. November 10.

19,617. M. Mithel. Improved exciting fluid for galvanic zinc carbon batteries. Complete Specification. November 12.

19,691. J. C. Lawson. An improved device for ozonising air or gas by means of electricity. November 13.

19,704. J. C. Richardson. Improvements relating to the application of depolarisers in electrolysis. November 13.

19,775. A. Biener. Improvements in diaphragms for electrolytic decomposing apparatus. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

20,102. A. S. Ravendale. Improvement in dynamo-electric machines. November 11.

1891.

10,977. A. de Meritens. Improvements in galvanic batteries. October 28.

12,322. A. J. Boulton. From J. H. Bassler. Improvements in or relating to electrical welding. November 11.

15,575. A. de Meritens. Galvanic batteries. October 28.

16,187. H. H. Leigh. From J. B. Gardiner. Obtaining a fluid for primary batteries and utilising the waste products of such batteries. November 11.

16,522. W. P. Thompson. From C. L. Coffin. Improvements in electrically soldering or brazing metal. November 4.

17,003. A. F. Madden. Machines for making grids for secondary batteries. November 11.

17,430. D. M. Lamb. Electric batteries and materials therefor. November 18.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

18,224. W. Mills. Improvements in bleaching, deodorising, and purifying fats and oils, and apparatus therefor. October 23.

18,579. P. R. de F. d'Humy. Improvements in the manufacture or treatment of soap for toilet, washing, medical, and other like purposes, and in apparatus for holding or containing soap, and supplying same for personal or other uses. October 28.

18,632. F. G. Haigh and W. C. Haigh. An improved fluid soap. October 29.

18,675. J. J. Mann. Improvements in or applicable to toilet and other soaps. October 29.

18,731. A. G. Smith. Improvements in soap. October 30.

19,097. R. Hunt, E. S. Wilson, and E. Stewart. Improvements in treating crude cotton-seed oil to obtain oil, soap, and colouring matter. November 5.

19,297. J. Taylor. Improvements in the manufacture of soaps. November 7.

19,507. J. Taylor. Improvements in the manufacture of soap. November 11.

19,779. A. W. Hayles. A new or improved sharpening oil. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

19,382. J. Taylor. Treatment of soap-makers' waste lyes for the recovery of glycerin and other substances. November 4.

1891.

92. C. W. Kimmins and T. Craig. Separation or treatment of fatty or greasy matters from the wash-waters of wool-washing or scouring establishments. November 11.

101. W. H. Willcox. See Class I.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

17,966. T. Christy and C. Weygang. Improvements in the manufacture of materials for use as substitutes for gutta-percha, rubber oil-cloths, and other water-resisting articles, impermeable tissues, and for other purposes, and the application of the products to various uses. October 29.

18,072. W. P. Thompson.—From A. Freiherr (Baron) von Pereira, Germany. Improvements in or relating to the manufacture or preparation of resinous paints. Complete Specification. October 21.

18,310. E. Casper and W. Sowerby. A new or improved manufacture of paint, polishing material, and cements. October 24.

18,566. M. Williams. Improvements in the manufacture of laundry blue. October 28.

18,693. W. Smith. Improvements in the manufacture of white lead by the acetate of ammonia process, and more particularly in the preparation of the acetate of ammonia to be used therein, or for other purposes. October 29.

18,709. T. H. Copley. Improvements in the treatment of lead ores and the production therefrom of white lead, salts of and colours of lead, as also simultaneously zinc white. October 30.

18,895. C. H. Mathews.—From E. S. Mathews, United States. An improved compound for coating ships' bottoms, piles, and structures subject to the influence of sea-water. November 2.

19,545. E. V. Gardner. Improvements connected with the manufacture of white lead. November 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

16,093. R. W. E. MacIvor and W. Smith. Improvements in the production of "white lead" or basic carbonate of lead, and apparatus therefor. November 18.

16,916. T. Drake. A new turpentine and means of producing same. October 28.

19,323. W. Smith and W. Elmore. Manufacture of basic carbonate of lead or white lead. November 4.

19,784. W. Smith and W. Elmore. Manufacture of basic carbonate of lead or white lead. November 11.

1891.

684. W. Jstrop and A. H. Parker. Improvements relating to the manufacture of carbonate of lead, or white lead, and to apparatus therefor. November 18.

1145. J. Campbell. Composition for coating tin and other like vessels. November 18.

13,429. J. Knowles. Improvements relating to laundry blue. November 11.

14,160. A. McCowatt. Improved anti-fouling composition for ships' bottoms. October 28.

16,098. J. C. Fell.—From C. A. Stevens. Manufacture of white lead. November 4.

17,221. E. Binney. Manufacture of lamp black, carbon black. November 18.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

18,003. F. J. Bagg. The manufacture of an improved composition leather fabric. October 20.

19,397. I. Goldschmidt. Improvements in the process of dyeing, tanning, and mordanting leather, tanned fabrics, or other porous materials, and in apparatus employed therefor. November 10.

19,637. E. Edwards.—From H. Bauer and J. Syketta, Germany. See Class VII.

19,658. W. Francis and A. F. S. Grant. An improved vessel for tanning purposes. November 13.

COMPLETE SPECIFICATION ACCEPTED.

1891.

15,661. J. de Hessel. Method and apparatus for shrinking leather by means of fat. November 4.

XV.—AGRICULTURE AND MANURES.

COMPLETE SPECIFICATION ACCEPTED.

1891.

2168. W. Bowler. Improvements in the collection and utilisation of excreta, and in the preparation of manure therewith. November 11.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

19,257. E. W. Catford. An improvement relating to the process of coating and colouring sugar crystals. November 7.

19,762. R. Morton and T. Morton. Improvements in and connected with pans for boiling or heating sugar or compounds thereof or similar substances. November 14.

19,774. J. Y. Johnson. — From C. Pieper, Germany. Improvements in the manufacture of grape sugar and grape sugar syrup. November 14.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

18,258. F. L. V. Beanes. An improved process for treating grain to obtain a product suitable for use in brewing, distilling, vinegar making, and other purposes. October 23.

18,292. F. Scheidler. Improvements in apparatus for liporing sugar. October 24.

18,488. J. Sutton. An improved process for filtering beer and other liquids, and apparatus therefor. October 27.

18,511. A. Umbeck. Improvements in brewing. Complete Specification. October 27.

18,538. R. H. Leaker. Improvements in pneumatic maling and in machinery or apparatus therefor. October 28.

18,833. E. Barlow. Improvements in drying and calcining brewers' refuse and grains, and other substances and materials. October 31.

18,997. R. H. Leaker. Improvements in kilning malt and in structures and apparatus therefor. November 4.

19,748. F. L. V. Beanes. Improvements in apparatus for treating grain, rice, and the like for the obtaining of a product suitable for brewing, distilling, vinegar-making, or other purposes. November 13.

19,785. J. G. Slater. From the Companhia Fabril de Artefactos de Metal, Brazil. Improvements in distillery apparatus. November 14.

19,787. D. Rylands. An improved substitute for yeast. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

20,803. F. Fletcher. See Class XVIII., I.

1891.

852. F. Kong. Manufacture of champagne and other beverages charged with carbonic acid. November 11.

12,668. H. Elion. Improvement in the purification of yeast. October 28.

14,276. A. Bruns. Process and apparatus for the production of sparkling wines and other sparkling beverages. November 4.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

17,899. J. Kay. An improved method of preserving fruit. Complete Specification. October 19.

18,615. J. Quaglio. A process for roasting pure coffee whilst condensing the steam produced during the roasting operation in coffee substitutes or in sugar for the purpose of extracting the aroma and products therefrom. Complete Specification. October 29.

19,007. W. Flowers. Improvements relating to the admixture and treatment of certain ingredients for the production of a new article of food. November 4.

19,369. C. Chambers. An improved solidified jelly. November 9.

19,394. G. Reiss and J. Bauer. An improved preparation suitable for human food. November 10.

B.—Sanitary Chemistry.

17,844. A. Wollheim. An improved plan for the construction of works for the treatment of sewage and other foul or waste liquids. October 19.

17,924. A. P. Hope. Hope's process for oxygenating, deodorising, and disinfecting sewerage, sewage, or other fermentable or noxious matter. October 20.

17,925. A. P. Hope. Hope's process for oxygenating and disinfecting sewerage or other fermentable matter, and separating, clarifying, and precipitating same. October 20.

17,926. A. P. Hope. Hope's process for oxygenating and disinfecting sewerage, sewage, or other fermentable or noxious matter. October 20.

18,286. G. C. Purvis. New or improved method in sewage precipitation. October 24.

18,287. G. C. Purvis. New or improved method in sewage precipitation. October 24.

18,466. A. Lutschauig. Improvements in and connected with the manufacture of filtering, precipitating, deodorising, and purifying material. October 27.

19,120. J. P. Allott. Improvements in apparatus for dealing with the refuse of towns. November 5.

19,157. E. Grinshaw and H. Grinshaw. The purification of waste effluent waters from manufacturing processes. November 6.

19,395. H. Lockwood. Improvements in the purification of sewage and other foul waters by the employment of certain waste materials. November 10.

19,433. H. J. Rogers. An improved method of treating sewage. November 10.

19,739. T. Wardle. Wardle's patent process for the treatment of sewage and other refuse matters. November 14.

C.—Disinfectants.

18,118. F. O. Stow. New chemical compounds for fumigating and disinfecting purposes, to be known as "Thiophenylia and encephylphenylia." October 22.

18,434. S. B. Moss and T. F. Bourne. Improvements in sulphur candles. Complete Specification. October 27.

18,466. A. Lutschauig. See Class XVIII., B.

18,840. L. L. G. Baij. Improved apparatus for generating and disseminating vapours for perfuming and disinfecting the atmosphere, and for destroying noxious germs. October 31.

18,913. A. Lembach, F. Schleicher, and C. J. Wolff. Improvements in and relating to soluble quinoline antiseptics. Complete Specification. November 3.

19,379. B. Cailhefer, née Rafford, and J. Labadie. An improved liquid insecticide. November 9.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1890.

19,168. E. Luck, R. Pott, and N. Pott. Treatment of cereals for preventing or arresting decomposition, and for preserving or improving the condition thereof. November 18.

20,803. T. Fletcher. The preparation of diastase for use in the manufacture of bread and biscuits, and for other purposes. October 28.

21,006. E. Sonstadt. Extraction of malt and hops, and preparing a confection of the same. October 28.

1891.

16,909. A. D. McKay. Improved medicinal food. November 11.

B.—Sanitary Chemistry.

1890.

19,967. R. Cunliffe and E. Barlow. Improvements in method of and apparatus for treating towns', slaughter-house, and other refuse, or substances or materials. November 11.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

18,465. F. L. Jacob. Improvements in the process of manufacturing millboards and paper. October 27.

18,736. L. H. Grundy. An improved flock paper. October 30.

18,889. G. O. Tschaplowitseh. Improvements in washable writing material. November 2.

19,135. L. E. Vial. *See Class V.*

19,560. H. de Chardonnet. An improvement in the manufacture of pyroxylines. November 11.

19,783. G. L. Hille. Improvements in the manufacture of celluloid balls. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,169. W. P. Thompson.—From P. R. Thom. Improvements in apparatus for straining or screening paper pulp. November 18.

1891.

748. R. C. Menzies and E. J. Bevan. Manufacture of paper for cheques and like documents. November 18.

16,321. A. Bürkel and C. Osterwald. New manufacture of composition for blotting or absorbing liquids. November 18.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

18,329. H. R. von Dahmen. Process and apparatus for producing purest chloroform. October 24.

18,408. M. Conrad and F. Geromont. Manufacture or production of salicylic compounds of metylaniline, ethylaniline, *p*-anisidine, and *p*-phenetidine. October 26.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

17,221. C. Kolbe. Improvements in the manufacture or production of salols. November 4.

20,252. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co. Manufacture of chemical compounds. October 28.

21,006. E. Sonstadt. *See Class XVIII., A.*

21,291. W. W. Horn.—From F. de Nare, Comte N. Ney, M. Sannier, and G. Dambmann. An improved process for the production of camphor. November 4.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

17,967. G. B. Bradshaw. Improvements in photography. October 20.

18,592. E. Hackh. Improved device for photographing in bound light. Complete Specification. October 28.

19,565. J. Burgess. An improved method of producing coloured photographic pictures. November 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

21,059. G. F. Redfern.—From J. M. Jordan. Improvements in or connected with the production of photographic negatives. October 28.

1891.

1736. O. Imray.—From The Actien Gesellschaft für Anilin Fabrikation. New or improved developers for photographic pictures. November 11.

16,094. V. Mathieu. Process for producing photographic pictures, having colours resembling those of the objects from which they are obtained. October 28.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

18,439. C. Huclser.—From G. Gillischewsky, Germany. Process for producing a liquid substance for making fir star firework. October 27.

18,788. L. Bonneville. Process for separating phenol and its homologues from other substances, and for converting phenol and its homologues into nitro-compounds for use in the manufacture of explosives. October 30.

18,861. A. McDougall. *See Class VII.*

19,041. G. T. Clarke. Waterproofing matches, cartridge or firework cases, and the like. November 4.

19,068. C. H. Curtis and G. G. André. Improvements in the manufacture of gunpowder. November 4.

19,267. W. P. Thompson.—From E. Landauer, France. Improvements in or relating to the manufacture of explosive substances. November 7.

19,346. P. W. Masson. Time fuze for explosive shells. November 9.

19,478. W. Wunderlich. Improvements in apparatus for nitrating substances. November 10.

19,796. J. McL. McMurtrie. An improved fuze for explosive projectiles. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

298. E. J. Ryves. Manufacture of explosives, and apparatus therefor. November 11.

11,326. W. E. Gedge.—From The California Explosive Co. Improved method of purification of nitro-glycerin. November 11.

11,326a. W. E. Gedge.—From The California Explosive Co. A novel explosive compound. November 11.

PATENT UNCLASSIFIABLE.

COMPLETE SPECIFICATION ACCEPTED.

1891.

16,910. E. Dean. Manufacture of eucalyptus products for various useful purposes. November 11.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 12.—Vol. X.]

DECEMBER 31, 1891.

Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, K.C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond, F.R.S.
Wm. Crowder.	Dr. Hugo Müller, F.R.S.
James Duncan.	B. E. R. Newlands.
Dr. John Evans, F.R.S.	J. C. Stevenson, M.P.
David Howard.	A. Norman Tate.
S. H. Johnson.	Sir John Turney.

Ordinary Members of Council:

A. H. Allen.	E. K. Muspratt.
Arthur Boake.	T. L. Patterson.
Jno. Calderwood.	Boverton Redwood.
Dr. Charles Dreyfus.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.
Prof. R. Meldola, F.R.S.	William Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. F. Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	F. Hurter, Ph.D.
L. Archbutt.	C. C. Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	Ludwig Mond, F.R.S.
H. Brunner.	B. E. R. Newlands.
E. Rider Cook.	John Pattinson.
W. Y. Dent.	W. H. Perkin, Ph.D., F.R.S.
Chas. Dreyfus, Ph.D.	H. R. Procter.
Percy Gilchrist, F.R.S.	Boverton Redwood.
John Heron.	John Spiller.
D. B. Hewitt, M.D.	A. Norman Tate.
David Howard.	Wm. Thorp.
Prof. J. J. Hummel.	Thomas Tyrer.
Prof. A. K. Huntington.	

Editor:

Watson Smith, University College, London, W.C.

Assisted by the following Staff of Abstractors:

S. B. Asher Aron. IV., IX., X.	J. Walter Leather, XV.
H. Auer. VII.	Ph.D.
T. L. Bailey, Ph.D. Gen.Chem.	F. H. Leeds. III., XXI.
G. H. Beckett. V., VI., VII.	A. Liebmann, Ph.D. { IV., VI.,
D. Bendix. III.	XX. }
E. Bentz. IV., V., VI.	A. R. Ling. IV., XVI.
Jos. Bernays, M.I.C.E. I.	D. A. Louis. XV.
E. J. Bevan. V., XIX.	W. Macnab. XXII.
Bertram Blount. { IX., XI.,	K. E. Markel, Ph.D. ... XII.
XII., XIII. }	A. K. Miller, Ph.D. ... III., IV.
Arthur G. Bloxam XIV., XV.	N. H. J. Miller, Ph.D. XV.
C. H. Bothamley. XXI.	J. M. H. Muuro, D.Sc. XV.
E. G. Clayton ... { IX., XIII.,	H. S. Pattinson, Ph.D. VII., X.
XVIII. }	H. T. Penter. } XVI., XVII.
V. Cornish. VIII., IX., XIII.	mann.
C. F. Cross. V., XII., XIX.	F. W. Renaut. ... Patent Lists.

NOTICES.

Members are hereby advised that the subscription of 25s. for 1892, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation should reach the General Secretary not later than January 15th, 1892.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, January, February, and April 1886, and February 1889. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED. 23rd DECEMBER 1891.

Adeock, S. R., Minas de Rio Tinto, Prov. de Huelva, Spain, analytical chemist.

Allen, Edw. W., Dover Mills, Glossop, Derbyshire, paper-stainer's manager.

Bedford, Chas. S., Broomleigh, Chapel Lane, Headingley, Leeds, manufacturing chemist.

Coode, J. Charles, 19, Freeland Road, Ealing, W., civil engineer.

Davidson, Richd., 15, Lilybank Road, Dundee, oil-merchant's clerk.

Dixon, W. Hepworth, Fairfield Works, Bow, E., works manager, Bryant and May, Lim.

Durham, Hy., City of London School, Thames Embankment, E.C., chemical lecturer.

Dutton, W. H., 88, Wickham Road, Brockley, S.E., merchant.

Lastwick, Jos. H., Norristown, Pennsylvania, U.S.A., chemist.

Harrison, Dr. Franklin T., London, Ontario, Canada, public analyst.

Harvey, Sidney, South-Eastern Laboratory, Canterbury, analytical chemist.

Holland, Jos., Brewery House, West Gorton, Manchester, working brewer.

Jones, Daniel E., Montrose House, Tipping Street, Stafford, director of technical instruction.

Konigh, L. de, 325, Kennington Road, S.E., analytical chemist.

McGill, Dr. J. T., Vanderbilt University, Nashville, Tennessee, U.S.A., adjunct professor of chemistry.

Maerath, D., Kuala Lumpur, Selangor, Straits Settlements, manufacturing chemist.

Margetts, W. G., Woudham, Rochester, Kent, cement manufacturer.

Molesworth, F. H., Eton Street, Malvern, Adelaide, South Australia, analytical chemist.

Owens, Caroline, 88, Great Clowes Street, Lower Broughton, Manchester, dyer's manager.

Paul, Jas. H., 123, Palace Road, Tulsa Hill, S.W., analytical chemist.

Redwood, T. Horne, 2, Fisher Street, Red Lion Square, W.C., analytical chemist.

Sells, E. Perronet, jun., Broad Street, Ratcliff, E., coal merchant.

Williams, Seward W., 187 Central Avenue, East Orange, Mass., U.S.A., manager of Seabury Pharmaceutical Laboratories.

CHANGES OF ADDRESS.

Ashwell, H., 10 Sherwood; Langley Dale, Grove Avenue, Southey Street, Nottingham.

Barbour, T. F., 10 Glasgow; The Technical School, Coatbridge, N.B.

Barnes, E. A., 10 Charlton; c/o The National Explosives Company, Ltd., Hayle, Cornwall.

Butterfield, J. C., Journals to 13, Victoria Street, Westminster, S.W.

Doidge, H., 10 25; 6, Beech Avenue, Sherwood Rise, Nottingham.

France, H. C. D., 10 Quinton; 8, Vicarage Road, Edgbaston, Birmingham.

Goyder, G. A., 10 Adelaide; Ootalinka, Hawker's Road, Medindie, near Adelaide, South Australia.

Griffin, M. L., 10 Holyoke; Mechanicville, Saratoga Co., N.Y., U.S.A.

Hastings, H., 10 Malvern Terrace; Lavender Villa, Birmingham Road, Kidderminster.

Heywood, G., 10 Middleton; Beech Tree Bank, Prestwich, near Manchester.

Hogben, Walter, 10 France; 15, Pilrig Street, Edinburgh.

Hurter, Dr. F., Widnes; and (Journals) Holly Lodge, Cressington Park, Liverpool.

Jones, A. Fred, 10 Ibbique; c/o Walters Bros., Pisagua, Chili.

Lawrence, Jas., 10 Gibbstown; Repauno Chemical Co., Paulshorpe, N.J., U.S.A.

Leese, Jos., 10 Preston; Ettrick Bank, Birkdale, Southport.

Lenox, L. R., Journals to Chemical Laboratory, Navy Yard, Washington, D.C., U.S.A.

Marshall, Dr. T. R., 10 Birmingham; University College, Cardiff.

Mond, L., Journals to 64, Via Sistina, Rome.

Neil, Jas. M. (Journals), c/o Señor M. A. Herrera, Payta, Peru; and (subs.) c/o Collyer, Thirkell, and Bell, 141, Fenchurch Street, E.C.

Orr, Alex., Journals to c/o Mrs. Scott, Wallalong, Hinton, New South Wales.

Rawson, C., 10 Union Street; The Bradford Technical College; and (Journals) 2, Melbourne Place, Bradford, Yorks.

Riley, Jno., 10 Rawtenstall; Thornliebank, near Glasgow.

Savary, W. J., Holgate, 10 Surbiton; 39, Lombard Street, E.C.

Smith, Irwin J., 10 Chicago; 103, Tremont Street, Fairmount, Cincinnati, Ohio, U.S.A.

Williams, D., 10 Kurtz Bros.; c/o United Alkali Co., Gerard's Bridge Works, St. Helens.

Williams, W. J., 10 Camden; 1412, Van Buren Street, Wilmington, Del., U.S.A.

CHANGE OF ADDRESS REQUIRED.

Weldon, E., 10 64, Noel Street, New Basford, Nottingham.

Deaths.

T. W. B. Mumford at Glendale, Sylvan Road, Wanstead, Essex, December 26th.

Runtz, John, Linton Lodge, Lordship Lane, Stoke Newington, N.

Alex. Sutherland at Ballyclare, co. Antrim, December 21st.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: T. Tyrer.

Vice-Chairman: W. Crowder.

Committee:

C. F. Cross.
J. Dewar.
A. G. Green.
S. Hall.
C. W. Heaton.
J. Heron.
D. Howard.

W. Kellner.
B. Redwood.
W. S. Squire.
G. N. Stoker.
F. Napier Sutton.
Wm. Thorp.
T. E. Thorpe.

Hon. Local Secretary:

Communications to be sent to T. Tyrer, Stirling Chemical Works, Abbey Lane, Stratford, E.

SESSION 1891-92.

1892:—

Jan. 4th—Mr. Boverton Redwood. "The Galician Petroleum and Ozokerit Industries."

Feb. 1st:—

Messrs. J. A. Watklyn and W. Johnstone. "The Acids of the Fatty Series and certain of their Derivatives."
Mr. Watson Smith. "The Stability of certain Organic Nitrogen Compounds occurring in Coal-Tar Pitch."

Meeting held Monday, December 7th, 1891.

MR. THOS. TYRER, IN THE CHAIR.

A CONTRIBUTION TO OUR KNOWLEDGE OF THE SOLUBLE AND RESINOID CONSTITUENTS OF BITUMINOUS COAL.

BY WATSON SMITH, F.R.S., F.I.C.

Lecturer in Chemical Technology in University College, London.

In his most interesting Researches on Peat, published in the Memoirs of the Literary and Philosophical Society of Manchester, I think in 1871, the late Dr. R. Angus Smith gives an account of experiments made with the object of tracing the origin of the bituminous deposits or oil, found either in close juxtaposition to peat mosses or under them.

Dr. Angus Smith says, "It is known that on washing peat with ether, bisulphide of carbon, alcohol, or benzene, we obtain substances very rich in carbon and hydrogen. The origin of these compounds seems not to be the decomposition of the dead plant, but traceable with certainty to the living one (principally the *Sphagnum*). The resinoid substance is one apparently, like the resins in wood, resisting decomposition under water, and to a certain extent it thus accumulates, the woody fibre being washed away, and the resins being left to be greater in proportion than at first. This gives the reason why the *old peat* is so much richer than the *new* in these resinoids. If now the action be continued we have at last only the hydrocarbon matter left, the woody fibre being all removed and a hydrocarbon (resin or wax) left. Then after a further time the separation ceases, and resinoids begin to be washed away."

The observations of the late Mr. Binney, of Manchester, made it certain that oil flows from the peat. It may be and is extremely likely that the ozokerite, or earth-wax, is derived thus.

Oil has been found under a large heath in Germany, the *Lüneberger Heide*.

The solid resin, prepared by evaporating the solution in naphtha or ether, obtained by washing the peat, is hard and black with a fracture like wax. On the distillation of peat for oil this wax is obtained as a distillate, but by the means of solvent a crude product is obtained exactly as it exists in the peat. Several experiments showed a yield of 6 per cent.

The crude substance analysed gave: carbon, 73.39—73.55 per cent.; hydrogen, 10.78—10.49 per cent. The melting point was 57° C., but when purified this rose to 60° C.

When kept at the boiling point some time, more volatile matter came off. The composition now was carbon = 80.84—80.95 per cent.; hydrogen = 12.00—12.00 per cent.

Rapidly distilled a white solid product came over.

Slowly distilled, an oil with a pleasant odour.

142 grms. of the crude substance gave on distillation the following figures:—

At 100° C.....	No product.
At 200° C.....	1.5 aqueous liquid.
At 280° C.....	0.5 oil.
At 325° C.....	Boils, pungent smell of acetic acid.
At 352° C.....	39 cc. of oil and 2 cc. of water.

The specific gravity of the oil coming over below 350° was 0.857; above 350° was 0.819.

The oils of the distillate were mixed and analysed. Carbon = 83.86 per cent.; hydrogen = 12.70 per cent.

There were indications that these were allied to paraffin oils, but they contained no solid paraffin.

Professor Schorlemmer was certain that they contained a paraffin.

Dr. Angus Smith further extracted resinoids from peat and from the living mosses from the same place, and he found these resinoids similar, testifying to the probable correctness of his belief that these resinoids of peat are simply the residues from the moss plant left in the peat. Dr. Smith thus concluded that the resinous matter of peat had grown in the plant when fresh, and was not a product of decomposition.

Now with regard to coal, Professor Morris discovered spores and sporangia, and Professor W. Boyd Dawkins says, "No doubt the bituminous matter of coal is almost all derived from the spores and sporangia of fossil vegetation allied to the Club-moss. Our bituminous coal derives its bitumen from this altered resinous matter, first stored up in the fruits (spores, &c.) and afterwards more or less altered by the subterranean heat into bitumen."

In the Zeits. f. Berg. Hütten u. Salinenw. 1891, 36, 26 (this Journal, 1891, 753), an investigation by P. Siepmann is described of the soluble resinous constituents of coal. The particular coal examined was a Westphalian gas coal. Its composition was C = 80.31, H = 5.50, O and N = 12.94, S = 1.25. The coal was treated with different solvents, ether, alcohol, and chloroform, and three products differing both in properties and composition were isolated. The product extracted by means of ether amounted to 0.3 per cent., and formed a hard yellowish-brown resin with an aromatic smell. The alcoholic extract amounted to 0.25 per cent., and consisted of a dark brown resin with an aromatic smell and melting at 48°—50° C. It began to decompose at 100° C. The chloroform extract amounted to 0.75 per cent. It was a dark brown pitchy mass with a smell of coal tar.

It melts from 60° C. to 85° C., and decomposes at 145° C. Rammelsberg, in his "*Mineralchemie*," states that "A few per cents. of a dark resin may be extracted from cannel coals by means of ether, alcohol, and especially bisulphide of carbon, which resin is the cause of the caking of these coals." Siepmann's experiments show that the caking power of such coals is not *due to*, though it is influenced by, the presence of these soluble constituents (this Journal, 1891, 753—754).

M. de Marsilly asserts that all "caking coals" from pits in which firedamp occurs cease to swell up and cake when they have previously been heated to 300° C. Thus, after such a heating, when they are calcined in a state of powder, they will be found in a state of powder. Dr. Percy has confirmed this in the case of the strongly caking coals of Newcastle.

M. de Marsilly infers that the loss of caking property by exposure to air for a long time, and to the action of heat under 330° C. for a short time, are due to the same cause, viz., to volatilisation of the matter on which the property depends. This needs, of course, clear experimental proof. (Percy, Fuel, 308—309.)

I will now give the results of some determinations of the amounts of these peculiar soluble resinoid matters in various coals, chiefly cannel, which I have made recently. In course of this investigation I was invited also to examine a Japanese coal of bituminous character, and the extraordinary quantity of this peculiar resinoid or bituminous matter contained in that coal, has enabled me to extract information through experimental investigation, that with the minute yields of the other varieties of bituminous coals, was beyond my power.

At the outset, I had expected to be able to extract from the richest cannel coals the most bitumen by solvents, but I found this was a mistaken impression.

The solvent I employed was carefully rectified benzene, all of which distilled over between 80° and 82° C.

I did not care to employ a variety of solvents and to subject the coal to fractional treatment, as Herr Siepmann did, for I have as little faith in an attempt to isolate from such a product as this soluble bitumen chemical individuals by such means, as I have in similar attempts made with coal-tar. Hence I adopted benzene as my solvent, because I knew by experience that it possesses for such resinoid matters the largest and widest solvent powers. By extracting with benzene in large Soxhlet's extractors, and taking something like 20 grms. of the coal broken up to lumps about the size of large shot, treating for periods of about a fortnight, until in fact the droppings from the extractor were quite colourless, and distilling and evaporating off all benzene until no longer the odour of benzene was perceptible, and weighing the residual resinoids, the numbers subjoined were obtained.

RESINOIDS OR BITUMEN EXTRACTED FROM CANNEL COALS.

	Per Cent.	Odours.
<i>Scottish Boghead Cannel.</i>	0.6	Smells somewhat like "Astakki" of Russian petroleum, but fainter.
<i>Australian Cannel</i> (called by Professor Boyd Dawkins "Australian Boghead").	0.67	Almost odourless, on heating, faintly like petroleum.
<i>American Cannel</i> ("Rice-knarridge" Virginia).	1.06	Aromatic, rather pleasant, but of the petroleum character.
LANCASHIRE CANNELS.		
<i>Hucknall Cannel</i>	1.06	Both of petroleum character.
<i>Tyldesley Cannel</i>	0.85	

It is interesting to observe that the above-named Australian cannel was spoken of to me by Professor W. Boyd Dawkins as similar to the celebrated Scottish Boghead cannel, which was the subject of the celebrated old lawsuit based on the question "Is it, or is it not, a coal?" But here is the point of special interest, that whereas in the Scottish Boghead not a single fossil could be found to assist the plaintiffs in that case, in this Australian "Boghead cannel," Professor Dawkins did describe at any rate one species of definitely fossilised vegetable remains. Here also we see that the percentage of soluble bitumen is practically identical in both these cannels.

P. Sappmann found in his Westphalian gas coal 0.3 per cent. (ether) + 0.25 per cent. (alcohol) + 0.75 per cent. (chloroform). Total, 1.30 per cent. of bitumen.

We now come to the "pierre de résistance" of this inquiry, viz., the Japanese coal, already once or twice referred to.

Let me then say at the outset that an extraction with benzene in a manner precisely similar to that by which the other cannel coals were treated, yielded as an average 9.5 PER CENT. of resinoid matter or bitumen.

But though so much more abundant in quantity, the general characteristics, smell, &c., were much the same as those of the other bitumens extracted. If anything, the odour of the bitumen from the Japanese coal is more pronouncedly a crude petroleum odour. Just to show how fallacious was that old argument as to the similarity of the appearance of the Boghead cannel to solid bitumen or to a light coloured pitch, and its dissimilarity to coal, here

we find that the Boghead cannel actually contains only 0.6 per cent. soluble in benzene, whilst this Japanese coal, which does look like coal, and does not resemble pitch or bitumen to the eye, does contain more than ten times as much bitumen soluble in benzene!

Our interest being raised in this coal, I will now give you a short history of it, and its development for industrial uses.

It is, then, the product of a coal mine, known as the Miike mine, and the deposit is situated in 33° north latitude and 130° of east longitude, in the province of Chikugo, in Kiushiu Island, in the south-western portion of the Japanese Empire. It is close to the sea, and facing Shimabara Bay, as shown in the map on the wall—a very admirable example of combined ordnance survey and mineralogical investigation, which I commend to your inspection. It was presented to me by one of my Japanese students of chemical technology, Mr. Kitamura, of the Geological Survey of Japan.

This deposit was known 400 years ago, but the uses of coal being little known to the Japanese until comparatively recent periods, scarcely any importance was attached to its occurrence until 1873, when it was purchased by the Government at the request of its private proprietors. The reason it has been known for so long as a deposit, is probably that the strata in some parts have suffered such extraordinary upheaval, that the coal actually crops out in parts at the surface, or nearly so, the formerly over-lying strata having apparently suffered gradual denudation. In or before 1876, the Government appointed the Mitsui Bussan Kaisha, a branch of the house of Mitsui, sole agents for the sale of this coal, its object being to open and extend the consumption of Japan coal in foreign countries. The quantity then put out was only 300 tons per diem, half of which was composed of smalls, the rest being all large coal. The latter was used for coaling steamers, whilst the former was generally sold to salt works in the inland sea. In the year 1885, a new shaft was opened at a depth of 240 ft., and the production increased to 1,200 tons per day. In 1888 the Government sold the mine by public auction. Mitsui bought it for 4,550,000 dollars, or about 750,000*l.* The Government invested more than 1,000,000 dols. in machinery, pumps, &c., all of newest pattern, opened roads for transport by ponies, improved sea ports, canals, &c.

According to the Japanese survey, the area of the deposit is estimated to extend over 3,758 acres, containing some 85,441,000 tons of coal.

Since the mine was transferred to Mitsui, every new improvement has been introduced, including locomotive instead of horse traction, and the production increased step by step up to from 1,900 to 2,000 tons per diem.

From these facts we learn something of the highly intelligent interest taken by the Japanese Government, which, of course, means the Emperor or Mikado, in those matters which lie at the foundation of the commercial prosperity of his Empire, and likewise how readily the example thus set was at once followed in the far-sighted enterprise of Mitsui. Two excellent harbours were soon founded near the Miike deposits, viz., Kuchinotsu and Misumi. Kuchinotsu lies at the mouth of Shimabara Bay, and is about 24 miles distant from the mines. Misumi is only 18 miles from the mines. Tug-boats continually ply to these ports carrying the produce of the mines, and here sufficient stocks of coal are always kept to meet the demands of steamers.

A railway line runs through Miike, and is being extended to Misumi, the new harbour, whither all coal will eventually be sent. A new shaft, 400 ft. deep, is also being sunk for further extension of production. When appointed, in 1876, sole agents, Mitsui Bussan Kaisha opened a branch house in Shanghai. The Chinn Merchant Steam Navigation Co. was the first to use Miike coal, and was then soon followed by Butterfield and Swire, Jardine, Matheson, and Co., and most other important Chinese firms. Thus the coal was proved of excellent quality, and the Mitsui firm then opened branches in Hong Kong and Singapore, and sub-agencies in nearly all the ports in the East. As to specific quality, stress is laid upon its value as a bituminous and steam-

raising coal, and it has the character of being one of the best, if not the very best, in Japan. It will sound strange to us, but as a matter of fact, most of the colliery labourers or miners are supplied by the Miike Prison, about 1,500 prisoners working under regular and systematic supervision, and under regulations established by Government. Not only are the most modern improvements in conveyance of coal adopted, but the mineral is subjected to all the refinements of systematic sieving, and, I believe, washing, just as in the most advanced British collieries.

The following statistics will add the last increment of interest in the development of this wonderful coal deposit in an insular country on the other side of the world, and possessing so many geographical and other analogies with our own, *except the earthquakes!*

Here follows the annual production and exportation of Miike coal since the year 1887:—

Year.	Total Production.	Export.
	Tons	Tons.
1887	392,105	165,561
1888	383,879	252,064
1889	444,966	276,883
1890	467,089	292,637
(From January to end of May.)		
1891	249,944	106,042
Estimated production for 1891.....		600,000 tons

I have read over nearly a score of reports on the character of this coal by users of it. Put before saying a word on these I observe that it is stated on excellent authority that the seam of coal of the Miike mines fully averages 8 ft. thick, that it is of uniform quality throughout and remarkably free from shale, and that the operations of the mines are under the supervision of a British engineer. As to its reported character by users, I observe that for seven years it has been used and is much appreciated in sugar refineries. The Shanghai Electric Company, Limited, reports the consumption of the coal less than 3 lb. per indicated horse-power with high pressure non-condensing engines. On steamers, the consumption per indicated horse-power is stated to be 1.98 lb. to 2.15 lb. in one case, and in another the rate of combustion in compound marine engines is given as 2.3 lb. coal per indicated horse-power per hour, and it is added that this rate with a more modern type of engines would be much lowered. A Scottish shipping firm says: "The consumption was only between 2 or 3 tons per day in excess of our average consumption of Welsh coal." *Comparatively*, it is stated equally as good as Australian Newcastle coal, also, "the best steam coal used up to that time, except Cardiff or high-class Australian." In another report, "the ashes," are said to be "only about one and a half per cent. more as compared with Welsh coal," and "in point of consumption the difference in Miike is about 15 per cent. more than Welsh." Generally it is classed as nearly equal to the best Welsh steam coals.

But the most interesting report for us is, perhaps, that of Mr. Thos. Weir, of Shanghai, where he minutely describes its manner of burning.

The fact of the coal containing about 10 per cent. of bitumen, will now be borne out in the following practical experiences:—

"The Miike lump coal is highly bituminous, having a rather dull, rusty appearance. On first being put on the fire it gives off great volumes of black smoke (which could be burned with careful management and suitable arrangement of furnace), and softens almost like pitch, but soon hardens, cokes, and burns brightly, giving off great heat. When once the men know how to use it, it proves one of the best steam coals in the Shanghai market," &c.

I have now only to supplement this information by the results of experiments, in which I have been throughout greatly aided by two of our students of chemical technology in University College, Messrs. J. C. Chorley and E. C. C. Baly, as well as by my assistant, Mr. Hamilton.

The coal is not quite black, and on pulverising it yields a powder of a dark-brown shade. The character is that of a highly bituminous caking coal. The determination of specific gravity gave a mean of 1.269. The fully-burnt ash of the coal is only of a reddish white tint, and the coal is thus intermediate between a white and a red-ash variety.

The amount of ash was given in two determinations as 9.34 and 9.55 per cent. Mean = 9.45 per cent. The calorific value of the coal determined in Thompson's calorimeter, and as the mean of four experiments was 7616 T. U.

An analysis of the ash of the coal gave the following numbers:—

	Per Cent.	
Silica	14.91	} With due corrections this 9.45 ash equals about 11½ inorganic matter as in the coal. And the error on the carbon in the coal analysis equals just 1 per cent. due to CO ₂ expelled from the CaCO ₃ .
Iron (Fe ₂ O ₃) ..	10.87 = 8.23 Fe	
Alumina	16.04	
Lime	42.38	
Sulphur	11.24 = 28.88 SO ₃	

The ash was alkaline; certainly quicklime was present. But also sulphides (probably CaS), for on treatment with hydrochloric acid H₂S was evolved. Here, then, was a case of naturally "limed coal," for undoubtedly a considerable part of this lime existed in the coal as carbonate. It may also be pointed to as a coal ash of very exceptional character, and as indicating that the coal plants and vegetation forming the coal must have been deposited not in and amongst the usual clays of those early periods, forming our present carboniferous "fireclays," but in a mixture consisting of a chalky clay (see Percy's Fuel, 278—279). It would be very interesting to analyse specimens of the fireclay contiguous to the deposits of this Miike coal. My belief is that it will not be true fireclay at all, but a chalky mixture containing some silicate of alumina.

Percy has shown that the ashes of coal closely resemble in chemical composition the fireclays contiguous to the seams, for no doubt those ashes represent the original clays with which the fossil vegetation had become mixed. These coal ashes thus consist chiefly of silicate of alumina. But this high percentage of lime may also indicate—and probably does—a formerly existing condition of soil in which the fossil plants grew, and if so, seeing that the character of vegetation is so much dependent on that of the soil in which it grows, the presumably special chalky condition of this soil may account for the luxuriant development of trees and shrubs, specially of the coniferous or other kinds, bearing spores and sporangia particularly rich in resins, which resins, being, like those of the more recent peat, more stable than the organised portions of the fossilising remains, have accumulated somewhat, and have remained evenly disseminated through the finally resulting coal, though undergoing *in situ* as it were, certain changes during the developments of subterranean heat in the process of fossilisation ("moulding"). Thus, I take it, the very composition of the ash, and its special character, points to a special character of the original vegetation, and makes it a matter, so to say, of less surprise that a coal of special characteristics has resulted.

It is of course not improbable that this Miike coal is really a lignite of advanced type, and this would seem the more probable from the cretaceous, or so tertiary character, indicated by the ash. Percy (Fuel, 317) mentions lignites from Auckland, New Zealand, and Tasmania containing resin diffused through it unevenly, in lumps in some cases which could be picked out. A portion dissolved in benzene. After drying between 110° and 120° it contained C = 81.6 and H = 11.06 (see p. 975). But no one can detect resin in this way in the Miike coal. It has not even a resinoid or pitchy appearance. It might provisionally be termed a lignitoid coal, but further one would scarcely be justified in going. The amount of gypsum found in the Miike coal was only 0.2 per cent. The amount of coke left on ignition in a closed space = 60.6 per cent.

Two analyses of the coal gave the following figures:—

	I.	II.	
Carbon	Per Cent. 75.22	Per Cent. 74.88	The true proportion of carbon is sufficiently nearly obtained by deducting 1 per cent. from the numbers given in the adjoining analyses.
Hydrogen.....	5.81	5.91	
Nitrogen.....	1.11	..	
Sulphur	3.15	3.13	
Moisture.....	6.62	6.65	

As I can easily show you, a splinter of the Miike coal readily ignites at the flame of a lamp and burns like a bit of candle. This led me to have a trial made of it as a gas-producing coal, and remembering that there is at the Salford Gas Works (Manchester) a fine working model of gas plant, I applied to my friend Mr. Francis Jones, who is the consulting chemist of the Salford Corporation Gas Works, and he kindly undertook to have the trial made for me.

RESULTS OF TEST IN MODEL GAS PLANT.

Make of Gas Per Ton of Miike Coal.	Illuminating Power.	Coke Per Ton of Coal.	Tar Per Ton of Coal.	Liquor Per Ton Coal.
Cubic Feet, 11,033	Candles, 23.42	Lb., 1,297 = 11.58 cwt.	Lb., 250 = 11.16 per cent. sp. gr. = 1.117	Lb., 250 sp. gr. 1.007 contains 0.53 per cent. NH_3

The tar was a perfectly normal one and contained 11.5 per cent. of light oils of sp. gr. 0.977.

But since it might be fairly urged that, to institute any valid comparison, some well known coals ought to have been tried in the same model under similar conditions, this objection was met by just such a trial.

The two following Lancashire coals and gas-coals were tried:—

Make of Gas per Ton of Coal.	Cubic Feet.	Illuminating Power.	Coke.
1. Ordinary gas-coal	12,033	Candles, 18.76	Lb., 1,562
2. Wagon coal	13,069	20.78	1,441

Thus, taking into account the yields of gas and also the candle power, it is, I think, clear that the Miike coal is fully equal to the Lancashire coals above-mentioned in gas-producing power. Moreover, the percentage yield of tar is exceptionally high, and the tar is decidedly good.

I think there is little doubt the 10 per cent. of bitumen must considerably contribute to the gas-producing powers of this coal, as it does to its flaming character. It will also be remarked that the coal contains bitumen in amount nearly equal to that yielded in tar when coals are carbonised in gas-retorts, viz., 10 per cent. The black smoke it tends to give off when freshly thrown on a boiler-fire is also thus explicable. But I have said it is a strongly caking coal, and it soon occurred to me to try how far the caking powers were modified or removed by prolonged extraction with benzene and removal of the bitumen. I found that thus the caking powers were diminished decidedly, but not destroyed. My experiment therefore tends to an agreement with that of Siepmann, and to show that at all events the caking power of the Miike coal is not more than partly caused by even so large a percentage of resinoids as 9.5 per cent.

Metallurgical Coke from Miike Coal.—An experiment was now made in the Simon-Carvès coke ovens of the Bear Park Company, Durham, by the kindness of the manager and Mr. Schroller, Mr. Simon's engineer and agent, in order to ascertain if the Miike coal is capable of yielding good metallurgical coke for blast-furnace use. The result was a good yield (60 per cent.) of an exceedingly dense, hard coke, splendidly adapted for resisting the crushing of the burden in the blast furnace. It contains, as just determined by Mr. J. C. Chorley, combustible matter = 83.88, ash = 15.80, and moisture 0.32 per cent. The sulphur amounted to 0.57 per cent. as CaSO_4 and 2.54 per cent. as CaS principally, a little only consisting of FeS . There is thus, other things being equal, a fine prospect for the development of the iron industry of Japan, especially as the coke used in Japan is at present got from Durham at necessarily great expense. In using the improved close coke ovens also, sulphate of ammonia will be placed at the disposal of agriculture, and the cresote oils from tar also obtained would be of enormous value in protecting wooden piles in harbour work, railway sleepers, &c., the former being at present ruined in an incredibly short time by the sea-worms.

The final question of interest is of course that of the composition of this bitumen so richly present in the Miike coal. By long extraction a quantity of the bitumen was obtained, and the benzene driven off from it. A semi-fluid, tar-like mass was obtained, smelling like crude petroleum. 47 grms. of the bitumen were taken, and distilled in a small retort. This means in percentages:—

Percentage Results.		Results of Distillation.	
Temp. C.	Per Cent.	Temperature.	Cc.
175° to 200°	3.2	175° to 200° C.	1.5 distilled over
250°	4.0	Below 250° C.	1.8 distilled over
300°	9.6	Below 300° C.	4.5 distilled over
Over 300°	21.3	Above 300° C.	10.6 yellow oil of greasy and thick character.
Higher Temperatures.	10.7	At higher temperature.	5.0 of thick red oil.
		Still higher temperatures to softening point of glass.	Red greasy matter and coked residue left. Sulphuretted hydrogen evolved.

23 grms. of coked residue left in the retort = 48.9 per cent.

The first fraction boiling between 175° and 200° C. was a clear naphtha, smelling just like petroleum naphtha, as you can perceive in the specimen here. The portion boiling between 250° and 300° was extracted with caustic soda for phenols, and the solution was treated with sulphuric acid, when certainly a phenol of higher molecular weight was liberated, smelling like pseudocumenol, as you may compare here. It soon turned dark-coloured on exposure to the light. The residual naphtha was now treated with a small quantity of sulphuric acid, and after separation with excess of soda, but no odour in the least indicative of the presence of the pyridine or quinoline series of bases, was manifested. The oil thus refined by the action of soda and acid was redistilled, it came over most of it, below 280° C., and possessed most unmistakably the odour of petroleum lamp oil. A small portion of it, however, gave, with evolution of red fumes, a heavy oily nitro-product with nitric acid, smelling like nitrotoluene or nitroxyline. This indicates the presence of some aromatic hydrocarbons. Treated with a drop of bromine, the bromine was at once absorbed, and the liquid became colourless, but a very small further addition then caused, especially in diffused daylight, the evolution of hydrobromic acid.

The most remarkable fraction is perhaps that distilling just above 300° C., for on cooling, paraffin scale crystallises out abundantly. The 21.3 per cent. distilling over 300° C.

is thus an oil very rich in solid paraffin, and the oil drained off is quite analogous to the lubricating oils obtained from American petroleum, as the specimens I have here will show you. One of the most singular features of this bitumen is, then, that appearing in the fact that it contains 3.2 per cent. of a naphtha, boiling so low as 175° to 200° C., and that such a naphtha is therefore disseminated through the Miike coal as a natural product. Of course, a coal containing so much of such a bitumen may well smoke copiously when thrown on a red-hot fire.

Now, at first my idea was that this bitumen was the result of subterranean heat on a rich coal, followed by a kind of slow destructive and consecutive distillation, and absorption in the substance of the coal of the distilled matter. This view I consider untenable in view of the great homogeneity of this coal, and of this evenness of character we have given testimony already (page 977, col. 1). I believe, in short, this bitumen consists of the altered or bituminised resins, &c., of the spores, fruits, &c., of a former rich and afterwards fossilised vegetation, a further stage of what Dr. Angus Smith found in the case of the peat waxes and oil, as Dr. Percy analogously found in advanced lignites, and as is believed by Prof. W. Boyd Dawkins to be the case with ordinary bituminous coal. I shall be possibly asked, "Has this case of so rich a content of a petroleum-like substance really formed in a coal any bearing on the question of the formation of petroleum?" I reply: "Here are both coal and bitumen, with the constituents of the latter; you can yourselves see and compare." Practically, it is a crude petroleum; and if I propound the theory that this is one undoubted way in which our petroleum is derived, I have at least direct experimental results to show for the statement. But I shall be slow to assert that this is the *only* and true source of petroleum. Other theories, such as Mendeleëf's theory of igneous origin, or Zoloziecki's theory of formation from animal remains (this Journal, 1891, 753), though unaccompanied by any direct experimental evidence, may nevertheless possibly rank among contributory processes of petroleum formation. Nevertheless, in Zoloziecki's, Engler's, and similar theories, taken as the only true methods of explanation, I find this difficulty: Animal remains are nitrogenous, and, looking at the great stability of nitrogen decomposition products, tending to the formation of tars, &c., were this theory sound, I should expect to find more of the stable nitrogenous bases and other bodies in petroleum than can be found therein. Contrast, e.g., coal-tar and wood-tar (a high and a low-temperature tar), and bone-tar, the latter most highly nitrogenous, abounding in the stable pyroline, pyridine, and quinoline with still more complex bases. Then imagine a petroleum derived from vegetable and one elsewhere from animal remains; should we not expect analogous differences in respect of nitrogen content? But, do we find them? It is true we have the known differences of American and Russian petroleum, but these are chiefly hydrocarbon differences, and lack of solid paraffins in the latter with abundance in the former. I do not know of any differences of absence or scarcity of nitrogen in one petroleum and abundance in another. I would rather conclude, therefore, that no one organic source of petroleum can be dogmatically fixed upon, but that probably both vegetable and animal remains contribute, the former *greatly out-weighting the latter and diluting their effect*. Quite probably Mendeleëf's theory also points to a contributory source.

But let me, in conclusion, take it that the Miike deposit is uniform throughout, as so far found to be, and that the estimated amount of coal there, is given approximately correctly as 85,444,000 tons (page 976, col. 2), and taking the bitumen as 10 per cent. (soluble in benzene; of course there may be some little remainder insoluble in benzene) we have disseminated through this coal no mean quantity of a substance we should certainly call petroleum were it found similarly disseminated through sandstone, viz., no less than 8,544,400 tons, containing at 21 per cent. of thick paraffin oil, with 5 per cent. of solid paraffin wax (the proportions I estimate) 427,200 tons of solid paraffin wax.

I now propose to extract a large quantity of this interesting coal, with the object of getting about a pound or more of

bitumen, which I will submit to a closer investigation. I shall also try by submitting the coal to heat in a retort not exceeding 350° C., to see if I cannot distil off the bitumen in fractions, and still leave a fairly good coal. The character of such residual coal will also be a subject of inquiry. If I succeed in driving out my petroleum thus and collecting it by condensation, still leaving a coal behind, why should not the Pennsylvanian petroleum, at all events to a great extent, have been thus similarly derived from the vast contiguous beds of coal there, now anthracite, but once probably bituminous like the Miike coal, for as such deposits differ as to circumstances, so, we must remember, may the circumstances, degrees, and modes of application of subterranean heat differ. We may have the slow mouldering heats of decomposition and we may have the subterranean heat of igneous origin, and each varying in degree and character, accompanied or unaccompanied by the action of steam.

The question may be thus regarded:—In Pennsylvania we have anthracite and petroleum lying side by side, in Japan we have the coal with the petroleum in it. Is it, I ask, an unlikely theory that the Pennsylvanian petroleum was once embosomed in the Pennsylvanian coal now anthracite? If not, does not the present condition of the Miike coal of Japan contribute to support the probability of this theory? Even if a mountain range now intervene between the respective Pennsylvanian deposits referred to, such range might have been upheaved more recently than the formation of those deposits. I do not see that even such a circumstance need destroy the validity of the theory propounded.

DISCUSSION.

MR. ALFRED E. FLETCHER said that it was most interesting to watch the advances in our modes of treating coal with a view to utilising as far as possible the numerous substances contained in it. Coal was originally looked upon simply as something to be burnt, later as something to be distilled so as to produce gas and coke, and then lastly the tar with its allied products and the ammonia were collected. The development of this industry had been very great. There were many works now where the coal was treated simply for its coke, pitch, and liquid products. It might interest many who had not closely followed the gradual changes to know that in many manufactures that which was formerly a by-product, is now really the main product. This was the case in works for the distillation of coal, in certain alkali works, and in some iron smelting works. In one of these latter as much as 70,000*l.* of capital was involved in the mere condensation of the tar, its collection and distillation, and in dealing with the ammoniacal salts. On visiting an iron works recently he had remarked on the extreme complexity and extent of the tar department, and was told that a great deal more capital was involved in that branch and more profit made from the so-called by-products, than from the iron for the production of which the work was originally started. A similar progress was going on in connection with other industries, and as our knowledge increased the term by- or waste-product would become less common.

MR. F. H. PERRY COSTE said that the author, in referring to the resinous constituents found in Lancashire coal, had spoken of them as being derived from moss. He (Mr. Coste) supposed from that that Mr. Smith was referring to the bog moss (*Sphagnum*), which was well known to contribute largely to the formation of peat—the first stage; but in a later sentence he had spoken of the so-called club moss, which was really a *Lycopodium*. He would like to ask which the author considered to contain the resin. Next, he had suggested that the bitumen in the Japanese coal was derived from coniferous plants. If so, he would like to know whether any of the remains of such plants had been examined, and if so, whether there was extant any report by botanical experts on their character. He would also like to ask the author whether he could tell them in what stratum this Japanese coal occurred. Although most of the English coal was found in the "carboniferous" strata, it was of course well known that coal occurred in various strata; and assuming that the various European strata has been traced

right across to Japan, he would greatly like to know with which of these the coal-bearing stratum in Japan would correspond. When the author stated that he had found 42 per cent. of lime in the ash, it occurred to him that that fact suggested a cretaceous origin for this coal, and he gathered that the same idea had struck Mr. Smith. It was generally supposed that our coal was formed from peat occurring in a near-by country, but it had been pointed out that, although this theory might account for the greater part of it, there had probably been other methods of formation as well. There was good reason to believe that some of our coal deposits were due to a mass of forest vegetation being swept down a mountain side and sunk in landlocked seas, as well as to delta deposits; and the large amount of bicarbonate found by the author in this Japanese coal pointed to the probability of a similar marine origin. He was somewhat surprised to find that the author talked of there being no experimental evidence to support the theory of the animal origin of petroleum, since he (Mr. Coste) distinctly recollected having seen an account of recent laboratory experiments in which petroleum was formed from animal matter at a very high temperature and great pressure. (This Journal, 1890, 1119.)

Mr. BURTON BLOUNT said that he could confirm the last speaker's remarks. He also had seen the account of certain experiments which were carried out on fish oil, there being no doubt that certain paraffins were produced therefrom by distillation under suitable conditions.

Mr. D. A. SUMMERS asked if the percentage of sulphur had been determined in the coke obtained in the experiments at Durham, as this would have a most important bearing in its application for certain metallurgical purposes. He thought that it would be useful if the author could tell them the melting point of the paraffin obtained.

Mr. THOMAS CHRISTY supported the author in the view that the resinous bodies in Japanese coal were probably due to moss. He had brought with him samples of paper actually treated with peat and moss, and it would be seen on inspection that these samples were quite glazed by the action of the resin contained in the moss and peat. He would also point out that these resinous bodies rendered the paper practically waterproof, and therefore especially applicable for use in the salt industry.

Mr. FREDERICK HOOPER wished for further information in regard to the properties of the higher boiling point fractions obtained from the bitumen. It was well understood that by the distillation of coal-tar oils, certain heavy oils were obtained, and by the distillation of crude petroleum naphthas one got bodies of the vaseline order. He would be glad to know whether bodies of the tar oil type or petroleum residue character were found among the higher distillates of the oil mentioned by the author. Having found a phenolic body in the distillate of this bitumen, was it not natural to suppose that the oils obtained would be more likely to consist of the tarry bodies than of the vaseline bodies?

Mr. WALTER SMITH, in reply, said that he quite coincided with Mr. Fletcher's remarks, and would remind him of an analogous case, when, owing to the exertions of the late Dr. R. Angus Smith in conjunction with himself (Mr. Fletcher), another waste product became a most valuable article of commerce. He referred to the case of hydrochloric acid. He doubted not Mr. Fletcher, with himself, could easily recall in memory a period when all boats plying on the canal at Widnes required to be copper fastened, iron nails quickly disappearing under the action of the dilute hydrochloric acid of that canal. In reply to Mr. Perry Coste's inquiries as to the probable origin of coal, he rather thought that spec. bearing growths analogous to the Club-moss formed a variety referred to by Professor Boyd Dawkins. Beyond referring to the actual work and evidences of such writers as Angus Smith, Binney, and Boyd Dawkins, he himself did not attempt to specify any definite variety of plant or tree. Seeing that such a large quantity of bitumen

was present analogous in character to that derived from lignite, peat, and peat-mosses, &c., and bearing in mind the special character of the soil traced through the character of the ash of this coal, it appeared to him to be extremely probable that the trees and plants from which the coal was derived might have been those of similarly special character, and indeed such as were very rich in wood and fruits abounding in resins. There was no doubt those natural resins were stable, and that the vegetable matter was unstable. Of course the bitumen was the altered residuum of these resinous matters for the most part, as he took it. He had just been informed by Mr. Christy, however, that a variety of turpentine had recently been obtained from petroleum or petroleum residues. If so, this was additional and rather strong evidence of certain petroleum being formed from resins of vegetable origin. He would himself like to know more of the geological strata in which the Miike coal was deposited. He might remark, however, that certainly one shaft had been sunk 430 ft. Dr. Percy had found it difficult to draw the line between lignites and true coals, as they shaded into one another almost imperceptibly, and both geologically as well as in chemical and physical character. There could be no doubt, however, that the presence of so large a proportion of chalk pointed to a cretaceous stratum. With regard to the question of the origin of the coal, he had tried to avoid dogmatizing as to a special theory either for that or for the formation of petroleum. He thought the delta theory of the formation of coal was a good one, but at the same time he was equally prepared to admit that a great deal might also be formed by direct successions of growth and deposition. He also thought that the formation of petroleum was equally ascribable to various causes. As to the animal theory, he did not think that that or the fish oil experiments referred to by Mr. Perry Coste and Mr. Blount proved much, because oils or tarry substances obtained by igneous destructive decomposition went through so many phases, and differed so much and so widely according to the heights of temperature to which they were subjected during such destructive decomposition or distillation, and he would ask what were the temperature-conditions under which petroleum was formed in the earth? It seemed to him that Engler's theory, as an exclusive one, was more convenient than convincing, for nitrogenous matter under conditions and at temperatures at which it could yield such hydrocarbon and other constituents as were found in petroleum would not so almost completely dissipate its nitrogen as ammonia, but would certainly yield stable organic bases as well. He adhered strongly to the view that no one source of petroleum could be fixed upon, but that organic matters of various kinds, both animal and vegetable, contributed, and the latter largely over-balanced the former. He had not as yet determined the amount of sulphur in the specimen of metallurgical coke that was made, but he would get it done in time for its publication in the Journal. As to the bodies analogous to mineral lubricating oils, and of higher boiling points in the bitumen, if Mr. Hooper would afterwards inspect the samples before the meeting, he would see that there were specimens of high-boiling oils as well as lighter naphtha quite similar to those of petroleum. There was an excellent lubricating oil he had prepared from the bitumen, whose odour and character resembled those of petroleum products, and whose specific gravity was low. He also showed a specimen of pure paraffin wax from the same source, all naturally contained in the bitumen, and so in the coal itself.

THE SALT INDUSTRY OF INDIA.

BY MURRAY THOMSON, M.D., F.R.S.E., F.E.I. U.C.

Late Chemical Examiner to the Government of the North-West Provinces of India.

THE sources from which salt is obtained in India are four. I. By importation from England chiefly from Cheshire. II. By evaporation of sea-water. III. By evaporation of water from salt lakes, brine pits, and springs. IV. Rock salt from quarries and mines in the Western Punjab. From whatever of these sources it is obtained, it is made to pay duty and it yields a very considerable part of the total revenue of the Government of India, as no less a sum than nearly seven millions of pounds are derived from the salt duty every year.

In considering the salt industry, it is unnecessary to mention any further the salt imported from England.

II. The extraction of salt from sea-water is still carried on both on the east and the west coasts of India. The methods pursued are very primitive, but they are not altogether devoid of either knowledge or skill. The manufacture as pursued at two places may be selected as examples of all the others on the coast. These are at Balasore and Puri. These places are both on the east coast a little southward of where the river Hooghly falls into the Bay of Bengal. At Balasore artificial heat is employed to get rid of the water, while at Puri the heat of the sun only is used. In both cases the native salt-makers begin with as concentrated sea water as they are able to procure. At Balasore mounds of earth are constructed, and the top of each mound is hollowed out into the form of a basin. This basin is filled with earth, impregnated with salt obtained from the land round about which has been under the sea during high tides. When the basin is filled with earth sea-water is poured over it and allowed slowly to percolate, and to find its way through an opening provided with a rough bamboo pipe into a reservoir. The contents of this reservoir are then transferred to unglazed clay pots holding about two quarts each. These are fitted into a bed made of adhesive clay, and underneath this bed a fire is kindled, the fuel used being dry grass obtained from the neighbourhood. The boiling process is carried out for about six hours, when after cooling the salt crystals are ladled out, and then allowed to drain and dry. The cost of the manufacture by this process is very nearly 2s. a hundredweight. To this has to be added about 4s. for the Government duty, so that the salt can be sold for 6s. per cwt.

At Puri the manufacture can only be pursued during the dry warm weather from January to June. Large shallow pits are made about two-thirds of an acre in extent. These are filled by *baling* in sea-water during the hours of high tide. Other smaller pits are also provided, and these are divided by low mud walls. The heat of the sun slowly concentrates the sea-water in the larger pits, and then stronger water is run into the smaller excavations to the extent of one inch deep. In from four to nine days this amount of water has nearly dried up, when men enter the pans and tread the bottom. This process is repeated several times—that is, a small depth of water is let in, allowed to dry up, and then trodden. At the end of about 25 days a layer of salt fit to remove is found in the shallow pans. It should be understood that the whole of the water is not allowed to dry up; a mother-water is left in which the bitter magnesian salts are held in solution and thus separated from the sodium chloride.

III.—1. *From Salt Lakes and Brine Pits.*—The salt tract of India includes a large part of Rajputana, extending from the River Jumna between Delhi and Agra, westward and south-westward to the Gulf of Cutch. There are many salt-producing centres in this area, but the chief are those of the salt lakes at Sambhar and Didwana. The largest of these is Sambhar, a lake, when at its fullest, 20 miles long and 5 broad, but very shallow, mostly not more than 3 ft. It is a lake only in the rainy season; after the rains it is a hollow which receives the drainage of 2,200 square miles

of land, in which sand ridges are numerous. One of these, 100 ft. high, protects the lake from being filled up by sand blown by the prevailing winds. There are three theories put forward to account for the salt which exists in the soil all over this tract of India. 1st. That beds of salt exist deep underneath, and that these may be a link between the rocks of the Vindhian chain in Central India with the beds of rock salt in the Punjab. The rocks seen in the neighbourhood are schists and quartzites much disturbed, and like those of the Aravalli Mountains not far off on the west. A thorough geological exploration of the district has not yet been made. 2nd. That the country was at no distant period an arm of the sea, which, when it retired, left the salt-impregnated soil. 3rd. That the salt is brought in solution from the surrounding country, and the water evaporates, and there being no outlet to the lake the salt gradually accumulates, the case of the Caspian Sea and the Dead Sea in Palestine being similar. This last theory has of late obtained great favour.

Sambhar lake is partly in the territory of the Maharajah of Jeypur and partly in that of Maharajah of Jodhpur, but the saltworks on it were ceded to the British Government in consideration of annual money payments made to the respective native Governments.

Salt making or gathering begins in the month of March, and is carried on till the rainy season sets in, at end of June or in July. As the warm weather advances, through April and May, the lake dries up until hardly any water is left. The crusts of salt begin to be formed when the water of the lake acquires a specific gravity of 1.08.

The salt lies as a thick crust over the mud, from which it is separated by small intervals so that the salt gatherers can lift off the salt in cakes. The salt thus gathered has only to be dried to render it fit for sale. It needs no further purification, and it is much esteemed by the people. There is a good deal of waste in the gathering, but this waste salt is purified by solution, subsidence, and then evaporated and crystallised in small excavated pans.

The amount of salt produced at Sambhar is from 100,000 to 120,000 tons in a year.

III.—2. *The Brine Pits of Gurgaon.*—This district is the most easterly part of the salt tract already described. Salt has been obtained from these pits for several centuries by a process similar to that pursued at Sambhar. Of late the making of salt in Gurgaon has declined almost to total extinction. The chief reason for this is the occurrence of magnesium chloride and sulphate, chiefly the latter, which gives the salt a very perceptibly bitter taste. And now that the railways have so opened up the country, salt from other localities such as Sambhar, free from this objection, can be obtained in all the market towns; so that the Gurgaon salt is nearly unsaleable. Some years ago the Commissioner of Salt Revenue referred the question of this salt to me as a chemical expert to see if I could devise a process by which the Gurgaon salt could be purified from the magnesian salts. I made some experiments and hit on a process which was quite successful, but in practice it could not be worked out on the large scale. The plan was to treat the brine with slaked lime, which, in the course of an hour or so, by the help of agitation, converted the magnesian chloride and sulphate into the corresponding calcic salts and magnesia itself. These latter, along with the excess of lime used, were allowed to subside and the purified brine run off. It was then found by test to be quite free from magnesian compounds and yielded a salt devoid of bitter taste. I found that 2 per cent. of slaked lime was enough to effect this change. (Although this 2 per cent. of slaked lime left a large amount of it unaltered and unused, yet I found by experiment that less would not do. Trials with 1.0 and 1.5 per cent. were made, but in these the magnesia compounds were got rid of entirely. Two per cent., therefore, was the smallest effectual quantity of lime that could be used. In these results it seems to me we have an instance of the influence of mass in determining the formation of compounds, an influence which was long ago investigated by Berthollet and by Gladstone). The process fails on the large scale because the difference of cost of the salt that had to be purified and that of pure salt was so small that the cost of the lime exceeded it. A further

difficultly was the accumulation of the lime employed, as, unfortunately, no useful purpose for it could be found.

IV.—In the North-western part of the Punjab there is a range of mountains, the E. flank of which is on the River Jhelum, and the W. end abuts on the River Indus. This range of mountains is known to the natives as *Khaura*, and to the Europeans as the Salt Range. A small part of the range extends to the W. side of the Indus. The rocks comprising the range belong to the Silurian system, so that the salt found imbedded with them is the oldest, in a geological sense, of any known salt deposit in the world.

Further to the N.W., and at no great distance, near Kohat, other extensive salt deposits are found, but these, it is curious to say, belong to the Eocene groups of rocks. Salt has been obtained from both of these sources from time immemorial. It was in the time of the Emperor Akbar, 1550 that a tax was first levied on the salt obtained here. All through the time of the Sikh possession of the Punjab salt was extracted from these mountains. It is estimated that there is as much salt here as will, at the present rate of consumption, last for 10,000 years. The area yielding the salt is said to be 670 sq. miles, and the thickness of the beds 100 to 225 feet. The Sikhs got at the salt by making deep caves, rather than mines, and they worked these in such a rude way that tremendous waste of salt took place, and as no supports were left to keep up the roofs and walls, these often fell in and caused serious loss of life. Since the time the Punjab passed under British rule a much better and safer system has been pursued. And quite recently at the Kheura or Mayo mines a wire tramway has been introduced. This, along with other improvements, has rendered the mines quite safe, and the working much more profitable.

The salt from the Salt Range is very pure and occurs in large and small crystals. The colour is various: red, black, and grey. The red is that most valued. The salt is sent direct into the market from the mines; and to facilitate its export a branch railway has been made to connect the mines with the general system of railways.

The average amount of salt taken from these sources is about 10,000 tons a year.

The question of raising revenue by means of a tax on such a necessary substance as salt requires a short mention. The tax is justified:—1st, Because it is an old tax. It was extant long before the days of British rule, and was then, and is now, submitted to without complaint. 2nd, It is the only tax, of an Imperial kind, laid on the people of the lower classes, and only amounts to 5d. per head per annum.

As has already been stated, the tax yields between 6 and 7 millions of pounds each year. The exact figure, 1886–87, was 6,658,000*l.*

A word may here be said on the great Salt Hedge or barrier, one of the most clumsy and obstructive arrangements that was ever devised to help in the collection of a tax.

This hedge was rendered necessary because the salt tax was not, as it is now, the same all over India, but varied in different provinces, and to prevent smuggling this extensive barrier was constructed. At one time it extended from Attock, on the Indus, to the Mahanadi river in the province of Orissa, a distance of 2,500 miles. This distance, if drawn on the map of Europe, would extend from Moscow to Gibraltar. It consisted of an impenetrable hedge of thorny trees and bushes, supplemented by masonry walls and ditches, across which no vehicle, nor even a beast of burden could pass without detection. It was guarded by a small army of officers and men, 12,000 in number, who divided the hedge into about 1,700 beats, and these had to be patrolled night and day. Of course, this hedge gave rise to an intolerable interference with the traffic of the country and also to much annoyance and oppression to individuals. Although many miles of this hedge still exist, its use is now abandoned, as the salt duty was in 1879 equalised all over India, and so the necessity for keeping it up ceased to be. The duty is Rs. 2 per maund (82 *lb.*). It was temporarily raised Rs. 2½ in 1888. The normal duty (Rs. 2 for 82½ *lb.*) is very nearly equal to 4s. per cwt.

It has often been proposed to remit the tax on the salt used for cattle, it being thought that, although it might be

fair to tax the part of it used by man, yet it was considered hard that the keepers of cattle should have to pay a tax on the salt used by their beasts. The Government of India would willingly grant this remission were it not the fact that the people, especially of the lower classes, would soon take to eating cattle salt. Some years ago this question was referred to all the chemical examiners in India with the view of devising a way by which this salt could be so mixed that, although still usable for cattle, it would be unfit for human use. The problem, although it looks simple, has hitherto been unsolved.

The difficulties are: 1st. The salt must not be made to taste or smell too repulsively, for if that is not attended to the cattle will not eat it. It is allowed that cattle are nearly as particular as men, and indeed more particular than some men, as to taste and smell in their food. 2nd. The adulterant, if I may so call it, must be a non-volatile and incombustible body, for if it can be got rid of by fire, then cattle salt would soon be subjected to a good roasting, then redissolved and crystallised, and so fitted for human use. Again, inorganic colouring matters, such as potass permanganate, potass bichromate can, because of their poisonous nature, be used only in small quantity, and from such small quantities it is easy by crystallising and washing to separate the salt white and clean enough to be used by any human being. From this it will be seen how difficult a question it is, and why it is that all the chemists in India have failed in finding a means of overcoming the difficulty.

ON THE CONSTITUTION OF ORGANIC PHOTOGRAPHIC DEVELOPERS.

BY DR. M. ANDRESEN (BERLIN).

In the *Moniteur de la Photographie* (16, August 15, 1891), Messrs. Auguste and Louis Lumière have published an article of interest on those reducing compounds of the aromatic series which may be used as photographic developers. Now the results published in this article differ in various respects from results obtained by myself, and therefore it seemed to me interesting further to investigate the matter. The authors state that they have made it their business to discover relations between the chemical constitution and the developing power of organic compounds, and this gives me an opportunity to compare their researches with my own.

PAR. I.—The authors mentioned state that the compounds of the aromatic series which may be used as photographic developers contain at least two hydroxyl-groups, or two amido-groups, or one hydroxyl- and one amido-group in the benzene nucleus.

That such a rule exists is true; but the priority of its discovery may be quite another matter, and I may point to the fact that my own paper on para-amido-phenol as a developer (*Photographische Mittheilungen*, Heft 8, July 15, 1891) contains the following statement:—The faculty of developing the latent photographic image on silver bromide films commences with disubstitution products. It has further been ascertained by experiment that the great number of substitution products of the amido- and of the hydroxyl-groups must be specially taken into account. Moreover, I have stated that if this be correct, three types of developers may be obtained by substituting the amido-group (NH_2), or the hydroxyl-group (OH) for two hydrogen atoms of the benzene formula, viz.,

1. Diamidobenzene (Phenylenediamine)—

2. Amido-arybenzene (Amidophenol)—

3. Dihydroxybenzene—

Par. II.—It has been alleged, secondly, that the above is correct in the general only if the groups are held in the para-position. As regards this assumption, it is a known fact that the meta-compounds cannot be used as developers. Already Eder and Toth (compare Eder, *Die Photographie mit Bromsilber-gelatin*, &c., 104) have shown that resorcinol cannot be used as a developer. On the other hand, I myself have stated (*Phot. Mitth.* Heft 8, 1891) that neither *m*-amido-phenol nor *m*-phenylenediamine can be used as developers. But, at the same time, and contrary to what is alleged, I found that besides the para-compounds, the three ortho-compounds of the above given constitution are likewise developers. (Brenzatechin (Catechol) had already been recognised by Eder and Toth as a developer.) In addition to this, I have to state that I have used *pure* *o*-amidophenol and *pure* *o*-phenylenediamine in my experiments. To the best of my knowledge there does not exist a single organic compound of the ortho-position belonging to *Par. I.* which will not develop. On the other hand, it seems probable that the developing power of all para-compounds of this constitution has not been tested, and therefore *Par. II.* does not seem sufficiently substantiated, especially if we consider that the ortho-position has given us excellent developers in the benzene, and more particularly in the naphthalene series, *e.g.*, eikonogen, of the constitution—

The condition necessary for a substance to act as a photographic developer must evidently not be looked for directly in the relative position of the developing pairs of groups—

to each other, but depends, as I have previously shown repeatedly, upon whether the compound forms a quinone-like condensation within these groups, under the oxidising influence of the halogen silver salts, exposed to light.

Then it is alleged that these rules are only available for molecules consisting of several benzene nuclei, or of combinations of benzene with other nuclei, if the amido- or hydroxyl-groups are bound to the same aromatic nucleus. Now, I have remarked about benzidine (diamidodiphenyl) that it has in this respect the same properties as a mono-derivative, and therefore I have already proved that this substance is no developer. As regards the naphthalene nucleus the rule of Messrs. Lumière does not hold good, since compounds like—

exhibit vigorous developing power.

These authors state that the developing power is absolutely lost as soon as substitution of the amido- or hydroxyl-groups takes place, unless at least two of such groups remain intact in the molecule. My own results do not agree with this statement. I have already published the fact that para-amido-phenetol—

is no developer (*Phot. Mitth.* July 15, 1891). Moreover, previous to the appearance of the article referred to at the outset, I had experimented upon dimethyl-para-phenylenediamine—

These experiments have been repeated and carried further, and the following results obtained:—

1. *Dimethyl-para-phenylenediamine*—

2. *Dimethyl-para-amidophenol*—

3. *Para-amido-phenetol*—

4. *Hydroquinone-mono-ethyl ether*—

I have used only perfectly pure dimethyl-para-phenylenediamine and dimethyl-para-amidophenol, and errors which might have resulted from impurities were therefore excluded; and the fact that both these compounds are developers is entirely in accordance with their relation to oxidising agents (compare Wurster, *Ber.* 12, 526, 1803). The two other substances, viz., para-amido-phenetol and hydro-quinone-mono-ethyl-ether, show a much greater resistance to oxidising agents, not even silver nitrate oxidising them readily, and they do not reduce silver bromide either exposed or not exposed to light.

I will not omit to give the details belonging hereto. The dimethyl-para-phenylenediamine used by me had been prepared from nitrosodimethylaniline by reduction, and showed the correct melting and boiling point, viz. 51° C. and 257° C. respectively. A solution consisting of 1 gm.—

100 grms. of water, and 1 gm. of caustic soda, developed on a sensitometer plate in three minutes 19° W. with somewhat flat gradation.

The dimethyl-para-amidophenol employed, had been prepared by diazotising dimethyl-para-phenylenediamine, and by boiling the diazo-compound until no more nitrogen was developed, and by re-crystallising from benzene it was obtained in large transparent crystals, which melt at 74° C. A solution consisting of 1 gm.—

100 grms. of water, and 1.5 grms. of caustic soda developed on a sensitometer plate in three minutes 19° W. with good gradation. Both substances are less active developers than *e.g.* non-alkylised para-amidophenol, but that they possess developing properties is beyond dispute, and in face of this fact the statement in effect to the contrary which has been made is incorrect. But it becomes probable that the developing power of a compound containing only one developing pair of groups, will be entirely lost, if the hydrogen of a hydroxyl group present in the molecule is substituted.

It is further stated by the authors that it appears that substitution of the hydrogen atoms of the benzene nucleus does not destroy the developing power. This statement is already to be found in an extended form (*u.*) in an article on eikonogen (*Farbenindustrie*, 1889, 184).

The nucleus substitutions of a compound which develops the latent photographic image have, as a rule, no

great influence on the developing power, but they often affect the physical properties of the substance in such a high degree that its practical application depends upon them. Amidonaphthol, *e.g.*, of the constitution—

is almost insoluble in water, whilst the sodium salt of the sulphonic acid of this compound, *viz.*, eikonogen, is sufficiently soluble for practical purposes.

The authors, Messrs. Lumière, have found that the carboxylic acids of developing substances treated with carbonates of alkalis cannot yield their full developing power. This observation I can confirm. The sulphonic acids of developers of the benzene series, *e.g.*, para-amido-phenol-sulphonic acid—

show similar properties. Caustic alkalis must be applied, in order to increase the reaction, whilst, *e.g.*, the corresponding developer of the naphthalene series, eikonogen—

is known to obtain its full developing power by carbonates of alkalis.

But they further state that the above rules can be applied only to the aromatic series. As far as I know, no photographic developers have hitherto been discovered among the corresponding compounds of the fatty series.

Again, they state that *phenylhydrazine*—the developing powers of which were first pointed out by Prof. Jacobsen—should be regarded as forming an exception. This is correct; but I may point out that a certain similarity exists between its constitution and that of the diamines of benzene, *viz.*: *Paraphenylenediamine*, $\text{C}_6\text{H}_4(\text{NH}_2)_2$; *Hydrazine* (diamine), NH_2NH_2 ; *Phenylhydrazine*, $\text{NH}_2\text{NH}\cdot\text{C}_6\text{H}_5$.

Para-phenylene-diamine and phenylhydrazine are known as developers. With the hydrazine (diamine) of Curtius I experimented as to its developing properties, with the result that this substance is really a developer if used with caustic alkali, but only in a slight degree; and it is therefore of hardly any importance, especially as the film, similar to that of hydroxylamine, shows an inclination to wrinkle.

Hydrazine compounds have the two azo-valencies connected amongst themselves, whilst in para-phenylene-diamine each of them is separately bound to the benzene nucleus. An exactly similar relation exists between para-amido-phenol and hydroxylamine, *viz.* :—

may be regarded in a certain sense as developing pairs of groups in a free state. The third developing pair of groups, dihydroxyl, described in the handbooks of chemistry as peroxide of hydrogen, is known to be under certain conditions a strong reducing agent. On the other hand it belongs to the

powerfully oxidising substances, as it easily gives off a portion of its oxygen. On account of these two properties this substance is of great interest to photographers, and I am at present engaged in testing the properties of hydrogen peroxide for developing or weakening the photographic image.

SESSION 1891—92.

1892:—

Jan. 13th.—Mr. A. E. Fletcher. "Modern Legislation in Restraint of the Emission of Noxious Vapours."
Feb. 3rd.—Mr. J. H. Dugger. "The Manufacture and Industrial Value of Aluminum and its Alloys."
Mar. 2nd.—Dr. G. Shack-Samner. "Bill for the Sale of Agricultural Fertilisers and Feeding Stuffs."
Apr. 6th. Chairman's Address. "Manuring for the Production of Fruit."

Meeting held on Wednesday, December 2nd, 1891.

MR. A. NORMAN TATE IN THE CHAIR.

FUEL PURIFICATION.

BY PERCY RATESON.

THE subject which I wish this evening to bring before the members of this Section is one which is of moment, not only to chemical manufacturers, but to all large consumers of fuel. Although every one who uses coal is well aware that the quality thereof is a matter of some importance, few, I think, fully realise the difference in actual value between a pure and an impure article. Most manufacturers believe that the purification of such a large volume of material would inevitably increase its cost to them, and it is only in a few isolated instances, such as the mixing slack for use in making black ash or crude soda, that they deem it worth while stipulating for a low percentage of impurities. Now I hope to be able to put before you the actual loss incurred by the use of such fuel, and also to show that it is within the power of the coal-owner to produce a comparatively pure article at possibly a less cost than he has to charge for the coal at present supplied, or at an increased cost insignificant compared with the benefit to the consumer.

I would respectfully urge on the attention of the coal proprietors that it is of the utmost importance to the manufacturing industries of this country that they should endeavour to turn out the best article at as low a price as

possible, as the commercial supremacy of this country depends to a great extent upon cheap fuel.

Dr. Redfern, in a paper before the British Association, considers that "under the term coal, those substances must be comprised which consist of compressed and chemically altered vegetable matter, associated with *more or less* of earthy substances, and capable of being used as fuel," with which definition I would venture to agree with the substitution of the words "a small quantity" instead of "more or less." That the quantity of earthy matter should vary it is impossible to deny, but that such variation should extend to the amount found in the fuel commonly met with, is beyond all reasonable expectation. In *Chemical Technology*, by Professors Miall, Green, Thorpe, &c., the mean composition of wood is given as: carbon, 49.6 per cent.; hydrogen, 6.1 per cent.; oxygen, 43.1 per cent.; ash, 1.2 per cent.; and of clubmoss as: carbon, 46.8 per cent.; hydrogen, 6.2 per cent.; oxygen, 42.1 per cent.; ash, 4.9 per cent. From these figures it is evident that when we find a coal containing up to 15 and 20 per cent. ash, some portion of the adjacent layers of earthy substances must have become mixed with the pure coal in the mining operation. Muspratt states the ash of lignite averages 5 per cent., and that of bituminous coal 1 per cent. to 2 per cent. How few samples we see nowadays up to this standard. The statement in Watts' Dictionary, that "the ash in coal varies from 1 to 30 or even 35 per cent.," is much nearer the mark, at any rate as regards that used in factories. I have noticed, and my observation has been corroborated by others, that since the great colliery strike, now nearly two years ago, the percentage of ash in the fuel supplied to manufacturers in this district has increased very considerably, and this is also accompanied by a rise in the price. It is no unusual occurrence to receive a consignment containing from 20 to 30 per cent. of ash, and I think I am not putting the average too high when I place it at 14 per cent.

This is a state of affairs against which it is time some action should be taken, and the recent formation of several powerful unions, or amalgamations, of fuel-consumers, renders possible the carrying out of a combined movement which should have every chance of success.

It is, however, useless to inform a seller of any article that his produce is becoming too impure for use, and must be improved or you will cease to purchase from him, unless you know that such improvement is possible, or that you can get a better article elsewhere at a relatively cheap rate; and the knowledge of your inability to do this has been until recently a sufficient obstacle to any action. But there is now, I believe, a process of coal-washing patented in this country, and available to all colliery owners, under the name of "The Lühlig Coal Washer," which enables them to so purify their coal, that the amount of ash may be certainly and uniformly reduced to 4 per cent. and even 2 per cent., and in so doing brings in a large profit to the colliery.

Apparatus for washing coal, as it is termed, is no new idea, and I find in Ronalds and Richardson, Chem. Technology, two illustrated descriptions of such machines used about 1855. Others have been constantly brought forward, but it has remained for Mr. Lühlig to perfect the process. His method has been largely adopted by the continental collieries, especially in Germany, and there has lately appeared an article in "Engineering," February 13, 1891, p. 184, illustrated by drawings, describing a large plant successfully at work at the collieries of Messrs. Merry and Cunningham, Limited, at Motherwell in Scotland, which treats the coal as it arrives over the bank, and delivers it automatically sorted and washed in railway trucks ready for market. I extract the following paragraphs from this article:—"With the increasing scarcity of good coal-beds in this country it has become necessary for coal owners and mine managers to pay more attention to improvements and labour-saving appliances in the treatment of the coal when above ground, in order to enable them to profitably work dirty seams of coal, avoiding at the same time all waste. . . . Coal-washing becomes therefore more and more essential, and is looked upon as the only means by which the dirt can be effectively

removed. . . . It has been made the subject of investigation by the North of England Institute of Mining Engineers. . . . Coal hitherto left underground, or sold as an inferior class, is made by this method into good marketable coal, and millions of tons may be thus added at an almost nominal cost to the available stocks. Two hundred plants have been erected by Mr. Lühlig in different parts of the world. . . . In Yorkshire the Denaby Main Colliery, Ltd., have erected a plant, principally for washing of coal to be coked, to enable them to produce a high-class coke from their very dirty hard and soft smudge. The result obtained is about 4 per cent. of ash in the coke" (equal to about $2\frac{1}{2}$ per cent. in the washed coal) "which is of excellent structure, the loss of pure coal in the refuse is only $\frac{3}{4}$ per cent., or practically speaking none whatever." I had the privilege a year ago of seeing this latter plant in operation, and I was assured by the manager the results were above all expectation.

I have been favoured by the Company working this patent with various particulars and descriptions of the plant, of which the following may prove interesting.

This process is the result of a long and varied experience with the most dirty classes of coal on the Continent of Europe, and is on the gradual reduction system, that is, it is not all crushed up in the dirty state, but is gradually broken up, the shale being automatically separated from the coal by degrees. It is not claimed that one type of machine will be suitable for every class of coal, but it is a process which can be so arranged as to meet the requirements and local conditions of each colliery. The system is, in short, a combination of new screening, crushing, and sizing machinery, improved washing machines, and new and greatly improved machinery for filtering the water used in the plant, so that it can be used over and over again. It is easy to wash nut coal, or even ordinary dross, but to wash fine coal (from $\frac{3}{8}$ in. down to dust) without losing more than 1 per cent. of pure coal and retaining only the fixed ash in the washed coal has hitherto been exceedingly difficult. This difficulty has been overcome (on a basis of 500 tons of fine coal being treated daily) at a cost of less than 1d. per ton.

The process essentially consists of:—

Dry separation of the run of the mine, that is, the mechanical separation of the slack or dross from the lump coal which, when requiring picking, passes on to picking and loading bands of an improved construction, producing as little "smalls" as possible.

Breaking the larger pieces of coal (interstratified with shale or mixed with pyrites) picked out on these bands to nut sizes, and separating the nuts, peas, &c., thus produced from the dirt in the following washing operations.

Sizing the coal from 4 in. downward in revolving screens for the production of nut, pea, and fine coal.

Washing the different sizes of nut coal coming from the revolving screens separately.

Recovering the mixed or finely interstratified coal (separated by washing from the pure coal and clean refuse in one operation) by crushing and rewashing.

Washing the fine coal from $\frac{3}{8}$ in. downwards (after being graded in grading boxes) on separate washers especially constructed for the treatment of fine coal, their work being perfected by the help of felspar; this was first employed by Mr. Lühlig in coal-washing machinery and has given the most satisfactory results.

The recovery of the sludge, or the finest coal dust carried away with the washing water, by means of automatic and continuous sludge-recovering machinery.

Clarifying the water used in washing to such an extent as to enable its use over and over again.

The automatic transporting and storing arrangements of the various products, nut, pea, pearl, and fine coal, and also of refuse.

Recovery of by-products, as, for instance, pyrites or brasses, which, in many of Lühlig's plants, pays the cost of labour of the whole plant.

Arrangements are also made for automatically storing a considerable quantity of coal, the hoppers being so arranged that a large quantity of coal can be loaded in a short time.

The dry separating portion of the plant is constructed so as to make as little "small" as possible, the screening and loading arrangements being economical, efficient, and automatic.

The washing arrangements are such that as much clean nut coal can be extracted as possible, and that three products can be made by each machine, viz., clean nuts, seconds or nuts (finely interstratified with shale) which are raised, crushed, and re-washed, and refuse free from coal. In all of Lübrig's plants there is a marked desire to avoid crushing all the coal, that is, the dirty and clean coal, together.

Very often coal from seams with a band, or badly interstratified with shale, is left in the pit; this coal can often be raised at a nominal cost, and treated by this process to yield a good marketable article. In the case of a Scotch colliery, the gain in this way amounts to from 2d. to 4d. per ton, and the work of each collier can be increased by half a ton per day.

The chief points worthy of notice in this process of coal-washing are—

The process is automatic and continuous.

The cost of working is almost nominal.

The quantity of water necessary is small.

The percentage of lump coal is considerably increased by careful handling.

The value of nuts and peas is raised.

The fine coal can all be saved and used for coke manufacture or for making briquettes.

Settling ponds are entirely done away with, the "smudge," or fine coal, being recovered by special machinery.

The cost for repairs is practically nominal, the wearing parts being few.

Coke made from washed coal is of increased value.

Several collieries in Saxony and Westphalia which paid no dividend before have, owing to the adoption of this process, been transformed into valuable dividend-paying concerns.

Among the other losses incurred through the use of impure fuel, that of transport may be reckoned.

At one colliery 18 tons of mixed coal are daily thrown upon the shale tip or waste (being 5,400 tons per annum). By this process marketable coal to the amount of 4,428 tons can be produced from this waste coal, worth from 3s. to 4s. 6d. per ton, at a nominal cost.

By careful handling and loading arrangements devised at this colliery by Mr. Lübrig, the yield of lump coal has been increased by 6 per cent.

This washer can be made to produce four different sizes of coal, though this is not always the case, in the following proportions—

	Per Cent.
Trickle and double nuts, 2 in. to 1½ in. and 1½ in. to 1 in.	41·84
Single nuts, 1 in. to ¾ in.	30·61
Peas, ¾ in. to ½ in.	16·21
Sludge, ½ in. to 0 in.	11·34

In a trial at the Maryport Colliery the coal was divided into two divisions, pearl coal and sludge.

	Ash.	Sulphur.
	Per Cent.	Per Cent.
Small coal before washing	11·78	1·35
Pearl coal after washing	2·78	..
Sludge	11·60	..
Pearl coal and sludge mixed	4·11	0·85

The proportions produced were pearl coal, 86·48 per cent., sludge, 13·52 per cent. 52 tons 13 cwt. treated gave 6 tons

5 cwt. refuse, containing 2·8 per cent. of coal. Another lot of coal at the same colliery—

	Water.	Ash.
	Per Cent.	Per Cent.
Before washing	5·24	22·41
After washing	4·94	4·48

The cost of washing at Motherwell is stated at ½d. per ton for labour, and slack, which formerly was sold for 6d. per ton containing 23 per cent. of ash, is now washed and sold for 3s. 6d. per ton, and contains only 2½ per cent. of ash.

The water used is given as 15 cubic feet per minute for a plant treating 800 tons per day of ten hours. The sludge is used at the Denaby Colliery for firing the boilers, not only in this plant, but throughout the colliery.

It may be urged, and with some reason, that this washed coal would probably contain an excess of moisture; but I am assured that this is not so, except in the case of the fine sludge, which latter you will notice only amounts to from 13 to 17 per cent. of the output. The arrangements in the washing plant are such as to drain the coal properly before loading by means of finely-perforated elevator buckets and storage hoppers.

It is of interest to find that in this process the nitrogen in the coal remains intact. The cost of treating the coal, though varying slightly according to the position, &c., may be fairly represented by the following figures for a 1,000 tons a day plant. Cost of plant and erection, 9,000l. :—

Depreciation at 10 per cent.	£ 900
Interest at 5 per cent.	450
Repairs, labour, and material	20
Wages process, oil, steam power, &c., 1½d. per ton	1,875
General charges, say	380
	<u>3,625</u>

on 300,000 tons this equals 2·9 pence per ton. The company working the patent in this country is the Lübrig Coal and Ore Dressing Appliances, Limited, 32, Victoria Street, London, who will give such explicit guarantees that a plant erected by them cannot fail to prove successful.

There is one exceedingly obnoxious impurity in coal which is eliminated to a large extent by careful washing; I mean the sulphur. At Kattowitz, in Germany, a coal containing 47 per cent. of ash, chiefly pyrites, is washed down to 5 per cent., and the residue used for making vitriol, which pays the whole cost of treatment. Doctors Playfair and de la Bêche, in the Government investigation, give the quantities of sulphur in various coals as under :—

Welsh, 1·42 per cent.; Derbyshire, 1·01 per cent.; Lancashire, 1·42 per cent.; Newenstone, 0·94 per cent.; Scotch, 1·15 per cent.; and others from 0·8 per cent. to 2·6 per cent. I venture to think that, at the present time, these percentages are somewhat exceeded, and that a fair average would be 2·0 per cent. An estimate of the consumption of coal in manufacturing operations in this country for the year 1877, I think gives the quantity as 80,000,000 tons. In the report of the Inspector of Mines for Manchester and district for 1889, the total output of coal for that year is estimated at, in round numbers, 177,000,000 tons. I think, therefore, we may take the amount used now in manufacturing operations as fully 120,000,000 tons. This at 2 per cent. would give 2,400,000 tons sulphur. In other words, there are annually poured into the atmosphere of this country 4,800,000 tons of sulphurous acid from the burning of coal alone, not to mention what is turned out in smelting and other processes, to which the much maligned sulphuric acid manufacture only contributes an insignificant 7,000 or 8,000 tons.

Mr. Ludwig Mond estimated, in his presidential address to this Society in 1889, that if one-tenth of the coal used in this country were treated for the production of ammonia from the nitrogen contained therein, we could be entirely independent of the supplies of nitrate of soda and other nitrogenous substances imported from abroad. From the above figures it is evident that precisely the same remark is true substituting sulphur for ammonia, and pyrites for nitrate of soda, &c. However, the prices of these materials are vastly dissimilar, and it is improbable that we could profitably make use of this sulphur; but, on the other hand, if we can simply keep even half of it out of the coal, and so from the atmosphere, are we not achieving a result of vast importance, to the health and comfort of our teeming population?

Dr. Angus Smith, in 1869, estimated the free sulphuric acid in the rain-water falling within the boundaries of the following four chief towns:—

London	0.33 grains per gallon H_2SO_4 .
Manchester.....	0.89 " " "
Liverpool.....	0.99 " " "
Glasgow	1.207 " " "

The sulphur is undoubtedly a very obnoxious constituent to the consumer of coal; existing as it mainly does in the form of iron pyrites, on ignition the iron is left as ferric oxide, which forms with the other matters a very fusible slag, stopping up the air channels, and causing heavy wear and tear on the fire-bars. In such industries as gas making, iron manufacture, and others, sulphur-free fuel would be of immense advantage. It is also often asserted that the spontaneous combustion of coal is caused by the presence of sulphur.

Now as to the actual gain in £ s. d. when using a washed slack containing, say 2 per cent. ash, against one with 14 per cent., which latter I have previously stated as a fair average. I have taken the following figures in both cases, not necessarily as authoritative, but sufficiently correct for comparison:—

	s. d.
Cost of slack delivered in waggons.....	7 0 per ton.
Discharging	0 1½ "
Firing.....	0 9½ "

Removing ashes, &c., at 1s. 3d. per ton of refuse. This comprises the uncombustible portion, together with 12½ per cent. as actual coal carried away unburnt, which I have found a reasonable percentage. For convenience I have calculated on 100 tons slack.

COAL CONTAINING 14 PER CENT. ASH.

	£ s. d.
Cost 100 tons at 7s. per ton.....	35 0 0
Discharging at 1½d. "	0 12 6
Firing at 9½d. "	3 19 2
Removing ashes, &c., at 1s. 3d. per ton on 15½ tons	0 19 8
Total cost of burning 84½ tons effective fuel....	40 11 4
or 9s. 7½d. per ton.	

COAL CONTAINING 2 PER CENT. ASH.

	£ s. d.
Cost 100 tons at 7s. per ton.....	35 0 0
Discharging at 1½d. "	0 12 6
Firing at 9½d. "	3 19 2
Removing ashes, &c., at 1s. 3d. per ton on 2½ tons	0 2 10
Total cost of burning 97½ tons effective fuel..	39 14 6
or nearly 8s. 1½d. per ton.	

Now, 9s. 7½d. — 8s. 1½d. = 1s. 6d. per ton of fuel gain in favour of the consumer.

Eighteenpence per ton is a very serious consideration in these days of keen competition, but there should be added to this something more representing advantages gained in ways which it is almost impossible to estimate, viz., increased efficiency of plant while working; less flue cleaning, and

consequent increase in output, owing to fewer stoppages; less wear and tear of fire-bars and plant generally; less locomotive power required, the number of full waggons to be manipulated being reduced by 14 in every 100, and of refuse waggons the same; saving in wages, beyond that given above in regard to the firing, in wheeling ashes from furnaces, and, in the case of mixing slack, less loss of insoluble soda, though, for my part, I believe this loss is generally over-estimated. I have stated before that I allow 12½ per cent. of combustible matter being carried away with the ashes. This may to some appear high, but I believe it is not so; and as one firm in Widnes have erected a plant for treating the ashes from the various departments of the works in order to extract this lost fuel, and, I am informed, with eminently satisfactory results, it is evident that the percentage of this combustible matter must be considerable.

In the Chemical Trade Journal for 13th December 1890 appeared a strong article on the adulteration of coal, stating that ordinary house coal, containing 19 per cent. of ash, was freely distributed, and in subsequent weeks several letters were published, corroborating this statement, and further asserting that 50 per cent. of ash was not uncommon. A letter signed "Coal Merchant," while not attempting to dispute the accuracy of the previous writers, set up the apology that the public would have a cheap article and they got it—nasty.

In the case of the alkali manufacture by the Leblanc process, in which the amount of fuel used makes the cost of that fuel of great importance, the saving per ton of 60 per cent. caustic would amount to about 9s., presuming that the figures I have given above are taken as a basis. Such a saving, when the competition of the ammonia-soda process is seriously threatening the industry, means the difference between success and failure.

Before closing this paper I should like to put before you a few points on the general position of coal-mining in this country.

We at present extract from the coal measures of the British Isles somewhere about 180 million tons per annum, and this amount increases yearly by some four or five million tons. At various times alarming statements have been made to the effect that we are rapidly coming to the end of our fossil fuel. Professor Jevons, some 25 years ago, gave the duration of the coal supply at about 100 years, and a Royal Commission was appointed to report on the matter. The inquiry was exhaustive and resulted in an estimate, that within a depth of 4,000 ft. there was sufficient coal to last for 276 years. Other calculations were given, based on different figures, but the one I quote was generally adopted, and it has been verified up to the present time, as far as the increase in consumption is concerned, in a wonderful degree. However, Mr. Henry Hall, Her Majesty's Inspector of Mines, in an address before the Geological Society of Manchester in November 1889, expressed the opinion that the available stock of coal has been over-estimated by the Commissioners, and that in his judgment the coal existing above this depth will become exhausted in 170 years from 1889. Besides, he casts a doubt on the possibility of working at 4,000 ft., asserting that even with good ventilation the temperature would be 115° F. It is urged that the increased difficulty of extracting the coal as the supply narrows will raise the cost, and therefore stop consumption. This is hardly borne out by history, for I find, in the Encyclopædia Londinensis, coal in 1536 fetched 2s. 6d. per chaldron in Newcastle and 4s. and 5s. per chaldron in London, which price was raised by a combination in 1590 to 9s. per chaldron, or about 3s. 2d. per ton. The consumption is not given at this period, but about 1810 it is stated as only 760,000 tons per annum in London at about 26s. per ton. At the present time London consumes more than this quantity in a month, at about 20s. per ton, though every year makes the coal more inaccessible. It is curious to find in this Encyclopædia the following statement:—"The Newcastle coal contains sulphur, which gives additional heat and spirit to the natural good qualities of the coal."

A Mr. Beaumont, in his Treatise on the Coal Trade, advocates strongly the conserving of our coal-beds by putting on an export duty, and the same policy is urged by

Mr. Ellis Laver in a letter to "The Times" in October 1888. Mr. Laver states the export as 30,000,000 tons per annum.

It is admitted, then, that the coal supply is limited, and even asserted by some that its exhaustion is probable in the near future. Other sources of fuel are looked for, and a number unhesitatingly decide for natural gas and oil. Mr. Charles Marvin, an authority on petroleum, in an article in the Newcastle "Daily Chronicle" in October 1889, boldly prophesies that within the coming five years petroleum will be so brought before the fuel consumers, both by its great superiority over solid fuel and its low price, that it will prove an exceedingly strong rival to coal, and he further states that there are over 1,000 steamers and locomotives in Russia and America using oil fuel, and that alone. Mr. Treguhart, in a paper read before the Institute of Mechanical Engineers on "Petroleum Refuse as Fuel," gives his opinion that the use of this refuse effects a saving of from 42 to 47 per cent. over coal, and asserts that there is no difficulty whatever in employing it; while a writer in the "Glasgow Herald" a few months previously, under the head of "Fuels of the Future," assures those interested in our fuel supplies that there is a sufficient reservoir of oil and gas beneath the crust of the globe to supply combustible material for untold ages.

However all these speculations may turn out, it is obviously our duty to future generations to endeavour to stop as far as possible the enormous waste of our natural resources. This waste occurs in many ways; but in connection with my subject there is one I wish particularly to bring under your notice. In the Chemical Trade Journal, 2, 1888, p. 126, an interview with a colliery proprietor is reported, in which he is asserted to have made the following startling statement:—"In getting 160 million tons of coal from underground, 50 million tons are lost to the nation, because it does not pay to bring it up, and therefore it is thrown down the 'gob' and left in a position in which it will be impossible to work at any subsequent time." We must hope that this quantity is exaggerated, but even so it is evident that the loss is very serious under this head. Now, I maintain that this can be altogether prevented, and a very large quantity of good fuel added to our supplies by treating in the way I have indicated, at a price remunerative alike to consumer and producer.

I have had my attention drawn to a paper by Professor Munro, or rather a leading article in "The Times" dealing with his paper, from which I gather that the Professor bids us be comforted regarding our coal supply, and, in fact, tells us to go on in the same way, for there is no danger ahead. But I hold it is better to make as sure as we can, for if the danger arrives there are no means of retracing our steps.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

Corrosion in Steam Boilers. J. H. Paul. Iron, Nov. 6, 1891, 401.

THIS paper was read at a meeting of the Society of Engineers, held on Nov. 2, 1891. The author first dealt with the molecular structure of iron in its two different forms of α -iron and β -iron, and the hardening effects of manganese and carbon, and touched briefly on the principal chemical properties of iron, including the action of caustic alkalis and the occlusion of gases by the iron. A short account of the manufacture of boiler plate led to the statement that the "vagaries of corrosion" is merely another way of saying that the molecular arrangement of the particles being invisible, it is impossible to say where the soluble particles lie, that is to foretell the particular spots where most solution will take place. Metals are collections of molecules massed together by fusion and pressure, and the very fact that they are seldom found free in nature, points to the conclusion that in their free state they are in an unstable state of equilibrium, and, therefore, ever ready to enter into fresh combinations.

The second part of the paper was devoted to corrosive natural waters, and rain water was traced from the sea to the steam boiler, the various causes which influence its character being briefly alluded to. Special reference was made to the Huddersfield tramway boiler explosion, and the

* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader **Lack**, Controller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

After a short description of the action of zinc, the paper concludes with an analysis of a piece of perished zinc taken out of a marine boiler.

PATENTS.

Improvements in Multiple Evaporating Apparatus.
T. Slaiter, London. Eng. Pat. 16,326, October 14, 1890. 11d.

In a horizontal cylindrical vessel in which a vacuum is maintained, the inventor arranges a number of horizontal troughs or tubes open along the top, and fitted into the two ends of the vessel. The troughs are connected at alternate ends to allow the liquid to descend from one to the other. Along the bottom of each trough are placed two tubes, one inside the other, with an annular space between them, within which steam circulates. The liquid entering the uppermost trough passes along the outside of the annular surface until, arriving near the end, it enters the inner tube, after traversing which it falls into the next lower trough and so on until it leaves the vessel below. Several vessels may be connected together for acting in multiple effect, and the shapes and arrangement of the troughs and tubes, as well as the method of their connection with and through the end plates of the vessel, may be varied

whilst all tubes and passages are arranged for easy removal. There are four claims and three sheets of drawings. (See also Eng. Pats. 10,493 of 1888 and 34 of 1889; this Journal, 1889, 759 and 970-971).—B.

Process for Obtaining a New Material from Bituminous Slate, and its Application as a Filtering Medium and as a Colouring Matter. J. Zeller, Esslingen, Germany. Eng. Pat. 17,218, October 28, 1890. 4d.

THE bituminous slate known as "Posidonien-schiefer" is ignited and afterwards slaked with water for the production of a special form of coke. The product is said to form an excellent filtering and clarifying medium equal to if not superior to bone-black. It can be used also in the manufacture of hot blacking and in the finishing of black textile fabrics as a substitute for kaolin.—O. H.

A New and Improved Apparatus for the Clarifying of Liquids. T. Thorp, Whitefield. Eng. Pat. 18,050, November 10, 1890. 8d.

THIS improved clarifier or filter consists of a rotary drum with a double bottom secured to a vertical hollow spindle provided at its lower end with a centrifugal pump which dips into the liquid to be filtered. The drum carries a number of concentric perforated partitions or screens, but the outer cylindrical casing is not perforated. It is by preference closed with a tight fitting cover, which has a gland in its centre through which the exit pipe passes. Filtering material, such as furnace ashes or charcoal, may be placed between two or more of the partitions. On the rapid rotation of the spindle, the centrifugal pump raises the liquid into the drum between the double bottom, whence it passes towards the circumference and is finally forced through the several partitions and filtering material to the outlet pipe. Three claims are made and the apparatus is illustrated by one sheet of drawings.—B.

Improvements in Apparatus for Heating and Evaporating Liquids. J. Kirkcaldy, London. Eng. Pat. 19,550, December 1, 1890. 11d.

THIS specification relates to details of construction of evaporating or distilled-water apparatus, in which evaporation is produced by steam-heated tubes or cylindrical vessels immersed in the water under treatment. The object of the invention is to secure easy access to all the surfaces on which deposits can accumulate. For particulars of the details, the specification, which is illustrated by five sheets of drawings, should be consulted. There are four claims.—B.

Apparatus for Agitating or Mixing Liquids, Washing the Interior of Casks and the Like, and for other Analogous Purposes. J. Bradbury and C. T. Colebrook, London. Eng. Pat. 20,684, December 18, 1890. 8d.

THIS invention is specially applicable to vessels having only one opening, e.g. a barrel. A series of levers and connecting links, forming an expanding framework, are arranged on a carrying bar and are actuated by a spindle. The apparatus when closed is inserted through the bung-hole, and the spindle, which is screwed, is then revolved by an external handle in order to expand or open the framework. On the spindle and carrying bar being then turned together the framework will revolve about the carrying bar at the centre and thus thoroughly mix and agitate the liquid in the barrel. On revolving the spindle in the contrary direction the framework is again closed and can be readily withdrawn from the vessel.—L. S.

Improvements in Filter Plates. R. Henton, Malaga, Spain. Eng. Pat. 12,316, July 20, 1891. (Under International Convention, March 2, 1891.) 8d.

THE object of this invention is to provide filter plates by which the extraction of oil from seeds, juices from fruits, &c., so that operations can be effected more perfectly and expeditiously.

The apparatus consists of a combination of filtering plates, some of which are provided with perforations, and so arranged that the liquid is separated from the solids by flowing between the adjacent surfaces of the plates, which are grooved, or roughened, or have a woven wire cloth placed between them to facilitate the passage of the liquid, whilst preventing that of the solid materials.—E. S.

A Centrifugal Machine for Incorporating or Mixing together Various Substances. C. H. Hanbold, Chemnitz, Germany. Eng. Pat. 10,738, June 24, 1891. 6d.

AN ordinary rotary centrifugal drum has arranged in it a number of sieves or perforated metal sheets. When the drum is rotated the materials placed in it are driven by centrifugal force against the sieves, and thus driven out are broken up for the purpose of being mixed, washed, or brought into intimate contact with one another, and collected in a chamber. The sieves are made of different materials and are constructed, according to the nature of the material to be operated upon.—E. S.

Improvements in Ore Sampling Machines. H. Le Roy Bridgman, Blue Island, U.S.A. Eng. Pat. 13,198, August 4, 1891. 8d.

IN this apparatus a kind of fractionation of the ore is effected. It consists essentially of three apportioning devices F, G, and H, each rotating in an opposite direction to the one immediately above it. The powdered ore is delivered through K into the shutles *h*, of which there are

SAMPLING MACHINE.

eight. Of these, one delivers into the shute *n*, another into *m*, and the rest into *p*, so that only one-eighth part of the ore passes into *n* and *m* respectively. The shutes *n* and *m* are not continued round the whole periphery of *G*, but only form one-fourth of its total area, consequently only one-fourth of the ore passing through *h* falls in *n*, that is one-thirty-second part of the original ore. The same applies to *m*. In the apparatus *F* the same sorting is effected, one fourth part of the ore delivered by *m* and *n* falling respectively into the corresponding shutes marked *m* and *n* and thence into the channels *B*¹ and *B*², whence they are delivered through the apertures *s*¹ and *s*². Two average samples, therefore, are obtained from these exits, each consisting of one-one hundred and twenty-eighth part of the total quantity of the ore passing through the apparatus. The rest of the ore falls through the apertures *p* into the shute *B* and issues at *s*.—H. K. T.

A Centrifugal Machine for Separating Acid from Nitro-cellulose or for other like Purposes. R. Kron, Gölzern, Germany. Eng. Pat. 13,612, August 12, 1891. 6d.

See under XXII., page 1029.

Improvements in or Connected with Filter Press Cloths. O. D. Droop, Havannah, Cuba. Eng. Pat. 16,581, September 30, 1891. 6d.

THE filtering cloth is about five centimetres longer than double the length of the filter plate, and having been folded double a seam is made two and a half centimetres from the upper doubled end. This seam forms the handle by which the cloth is lifted and hung over the top edge of the filter plate, half of the cloth then hanging over each side of the plate. By this means the cloths are regularly hung, and can be easily put on and removed as required. The bottom edges of the cloth can also be doubly or trebly hemmed, since the above arrangements effectually prevent any otherwise accidental folds of the cloth getting between the plates or the seam or hems.—E. S.

II.—FUEL, GAS, AND LIGHT.

Preparation of Oxygen, and its Application to Illuminating Purposes. G. Kassner. J. für Gasbeleuchtung, 1891, **34**, 351—353. (Compare this Journal 1889, 885; 1890, 187—188.)

WHEN ordinary coal-gas is burnt with oxygen, and the flame allowed to impinge on zirconium oxide, the intensity of the light produced is 40 times as great as that of an ordinary gas flame consuming an equal quantity of coal-gas; if, therefore, oxygen can be prepared on the large scale, even at double or treble the cost of coal-gas, it would pay to use it for the purpose mentioned above. As a matter of fact oxygen can be obtained in large quantities at a cost only slightly in excess of that of coal-gas, by the process briefly described below.

Porous calcium plumbate is first prepared by heating a mixture of lead oxide and calcium carbonate for about ten minutes at a red heat in a free supply of air; this operation can be carried out either in retorts or furnaces. The calcium plumbate is now allowed to cool down to a medium or dark-red heat, and then a stream of pure carbon dioxide passed through the retort or furnace as long as it is absorbed; in this way calcium carbonate is regenerated and oxygen is liberated, in accordance with the following equation—

The evolution of oxygen takes place in a continuous stream and in a very short time, the contents of the retort being at

the same time raised to a bright red-heat by the heat developed in the process; the liberated oxygen is almost free from carbon dioxide when the process is properly carried out, but if required quite pure it can be passed through moist, porous calcium plumbate heated at about 80—100°.

After expelling the oxygen from the calcium plumbate a stream of superheated steam is passed through the residual porous mixture of lead oxide and calcium carbonate, heated to bright redness; in this way the greater part of the carbon dioxide present in the mixture is recovered. Finally air is passed through the porous mixture of lead oxide and calcium oxide, heated at a moderate temperature, in order to reconvert it into calcium plumbate. The whole process is then repeated and can be continued for any length of time; the action of the calcium plumbate is, however, retarded if it is heated too strongly, as its porosity is thereby diminished. One complete series of operations occupies about 15 to 20 minutes.

Instead of employing pure carbon dioxide to liberate the oxygen, waste furnace gases, containing from 15 to 20 per cent. of carbon dioxide by volume may be used; in such cases instead of treating the calcium plumbate with carbon dioxide at a red heat, it is first moistened and then heated at 80—100° C. in a stream of the moist furnace gas, whereby it is converted into lead dioxide and calcium carbonate. This mixture is then treated with highly superheated steam, whereon the lead dioxide is decomposed with evolution of oxygen, the calcium carbonate remaining unchanged. The residual mixture of lead oxide and calcium carbonate can then be reconverted into calcium plumbate by heating it in a stream of air, in which case the carbon dioxide is lost; or it may be raised to a bright red heat (above 600°) and treated with superheated steam, the liberated carbon dioxide being collected; these two processes may also be combined.

After describing a suitable form of apparatus for carrying out the manufacture of oxygen in this manner, the author quotes the following advantages possessed by this, over Boussingault's barium dioxide process, as improved by Brin Brothers.

Calcium plumbate costs about one-third as much as barium dioxide and gives up the whole of its available oxygen, whereas barium dioxide yields only 8 per cent. of its available oxygen (compare Thorne, this Journal, 1890, 246—252). Calcium plumbate is not acted on by steam and is not rendered useless by carbon dioxide; it can be prepared in any kind of furnace or retort, whereas barium dioxide must always be treated in air-tight vessels.

No compression or exhaust pumps are required in the calcium plumbate process, and the cost of the plant and working expenses are less than in the case of the barium dioxide process. (See also this Journal, 1890, 108, 391, and 732.)—F. S. K.

The Naphthalene Question. E. Kunath. J. für Gasbeleuchtung, 1891, **34**, 529—534.

IN a paper read at a meeting of "Der deutsche Verein von Gas und Wasserfachmännern," the author discusses the conditions under which naphthalene is deposited from coal-gas.

Although it is frequently stated that an increase in the temperature of carbonisation is accompanied by an increase in the production of naphthalene, this statement is contrary to the author's experience; he considers that such an increase in the deposition of naphthalene is rather due to the fact that the condensers are not enlarged, although the make of gas is greater, and are consequently unable to fulfil their proper function. The deposition of naphthalene in a dissolved state is the more complete the more slowly the gas is cooled; that is to say, the longer it is allowed to remain in contact with the tar, the high specific heat of which prevents any sudden lowering of the temperature of the gas. (Compare this Journal, 1889, 949—954.) The statement of Brémond that solid naphthalene is not deposited from dry coal-gas is without foundation, as gas, dried with calcium chloride, behaves just like the moist gas. It was also found that the deposition of solid naphthalene is

not prevented by the addition of ammonia to ordinary coal-gas, a result which calls into question the statements of Friedleben and Tieftrunk on this subject.

For the deposition of solid naphthalene to take place it is not necessary that the coal-gas should be cooled below 0° ; a sudden lowering of its temperature by a few degrees is enough to cause a deposition even when the original temperature is as high as 16° C., so that the gas should be cooled gradually in its passage from the condensers to the purifiers.

The author then raises the question whether it would be advantageous to employ a further series of condensers after the gas has passed the purifiers; such a proceeding would of course be almost useless unless the surface of the water in the meters, holder-tanks, &c., were covered with petroleum or some such substance to prevent the re-absorption of aqueous vapour. Since the solvent action of the petroleum on the linings is a serious drawback to its employment, and no other liquid suitable for this purpose is known, it might be advantageous to place the condensers after the town's meter, and perhaps to lower the temperature of the gas by artificial means; if this were done, it would of course be necessary to cover the surface of the water in the traps and in the consumers' wet-meters with petroleum or replace the water by glycerin or otherwise to prevent any re-absorption of water. The advantages of such a thorough condensation would be that not only the deposition of naphthalene, but also the formation of hoar frost in the mains would be prevented; it is true that the consumer would get more light for the same money, the gas being denser, but this would be counterbalanced from the producer's point of view by a considerable saving in wages and materials, which are at present spent in removing stoppages, and also by an increased consumption owing to uninterrupted supply.

Some remarks were made on the author's paper by Hasse, of Dresden, in which he said that he could confirm Tieftrunk's statements on the deposition of naphthalene, and that ammonia and tar certainly do act as carriers of naphthalene. As regards the influence of the temperature of carbonisation on the production of naphthalene, he did not think it was appreciable. With reference to the author's experiments on the addition of ammonia to coal-gas, he pointed out that since the naphthalene is already mixed with tar and ammonia the experiment is not of much value. If the gas be treated with acids just before it passes into the purifiers, so that the ammonia present in various forms will be combined, a considerable deposition of naphthalene will be observed shortly afterwards either in the purifiers, station-meter, holder-pipes, or town's meter. The only way of avoiding the deposition of naphthalene is to cool the gas thoroughly, but as slowly as possible; this has been clearly demonstrated in the case of some gas-works at Dresden, opened 10 years ago; not a trace of crystalline naphthalene has been found either in the meters or in the town mains, owing to the employment of excellent condensers and of large pipes for distributing the gas. The size of the branch pipes must also be carefully chosen and the connections suitably arranged in order to avoid stoppages. Hasse does not believe in the addition of benzene to the finished gas, a course advocated by the author as a means of preventing stoppages, as the benzene is soon condensed again in another part of the mains.—F. S. K.

Flames. N. Tech. Jour. Prakt. Chem. 1891, 44, 246-255.

WHILE showing the explosion of coal-gas with the apparatus described by Heumann (Anleitung zum Experimentiren, p. 413), the author noticed a peculiar phenomenon, of which no mention is made in the work referred to. When the coal-gas is ignited at *a* (see Fig. 1), the gas then turned off, and the stopper *b* taken out the flame at first becomes larger; soon, however, it becomes smaller, at the same time diminishing in luminosity, and after a few seconds the yellow colour begins to disappear, a bluish zone becoming visible; then the whole flame becomes distinctly blue, and in it there is formed a second greenish conical flame which, becoming continually smaller, passes down the tube into

the vessel, and there ignites the mixture of gas and air. During the time that this flame is passing down the tube,

Fig. 1.

the original flame can be observed burning quietly at *a*, but with diminished luminosity.

It is clear, therefore, that under suitable conditions, a flame of coal-gas can be resolved into two parts, one of which continues to burn in its original position, whilst the other passes down the tube.

Fig. 2.

This phenomenon can also be observed with the aid of the apparatus shown in Fig. 2, which consists of a flask A (1 litre in capacity), provided with two tubes C and B (10 mm. in diameter).

Coal-gas is passed through the tube C, and after the air has been expelled from the apparatus a light is applied to *f*; if now the gas is turned off the same two flames are observed as in the case of Heumann's apparatus. If, however, at the moment when the two flames begin to separate, air is passed into A through C, the descent of the one flame in B is more rapid; if, on the other hand, coal-gas is passed through C shortly after the separation of the two flames takes place, the tube C being at the same time raised until its extremity is at *g*, the flame which was previously descending begins to rise in B.

The apparatus shown in Fig. 3 consists of a glass tube A (60 cm. long and 2 cm. wide), into which is fitted a funnel B (8 cm. in diameter at the broadest part); C is a glass tube (3 mm. in diameter), on which is blown a small bulb *o*, sufficiently large to completely close the funnel B.

Coal-gas is passed through the tube C, the bulb *o* being pressed close to the funnel opening, and the issuing gas is ignited at *f*; if now C is lowered a little so that air is admitted into A, the second flame begins to descend, and by moving C the quantity of air admitted can be so regulated that this flame is kept burning in any desired position in the tube A. The bluish flame, which continues to burn at *f*, has its convex surface turned upwards, whereas the much hotter, greenish flame in the tube has its convex surface turned downwards.

These experiments show that the ordinary flame of a Bunsen burner consists of two superposed conical flames of different heights, but having the same base; this is very clearly shown by holding wooden slabs in various positions

Fig. 3.

in the flame of a Bunsen burner, in which the difference in height between the inner and outer flames is as great as possible; Dessaga's, Maste's, and Terquem's burners are most suitable for this purpose.

The burnt figures obtained in this way show, not only the difference in temperature of the two flames, but also whether the supply of oxygen is obtained from within or from without the flame. In Fig. 4, for example, which shows the burnt impression of the upper flame, it is seen that carbonisation has taken place to a greater extent at the outer surface; in the case of the inner flame (Fig. 5) the contrary is the case.

Figs. 4 and 5.

Fig. 6.

Fig. 6 shows the burnt impression obtained by holding the wooden slab vertically in the flame.—F. S. K.

The Structure and Chemistry of Flames. A. Smithells and H. Ingle. Proc. Chem. Soc. 1891, 159—163.

THE authors have been engaged for twelve months in investigating the chemistry of flames produced by burning known hydrocarbons, and are still continuing their experiments. The publication of their results in the present form is consequent on the appearance of a paper by N. Teclu (see preceding abstract), who describes the phenomenon which served as a starting point in the authors' inquiry.

If a long glass tube be fitted by means of a cork over the metal tube of a Bunsen burner, so as to form a wider continuation of it, the flame can be caused to burn at the top of the glass tube. When the gas is turned slowly off, the flame becomes smaller, and develops a sharply defined inner cone of a greenish colour; this cone ultimately

becomes almost a flat disc of flame and enters the glass tube. It will, as a rule, descend at a rapid rate for some distance, then begin to oscillate, and finally either detonate and light the gas at the bottom of the metal tube, or else go out. If the gas supply be very carefully regulated, the flame may be got into such a state that it will descend the tube for a short distance and then re-ascend, and in this state it is very easy to see that whilst the lower cone is moving there remains at the top of the tube a steady cone of flame of a pale-lilac colour. By heating the glass tube at one point, so as to increase at that point the rate of inflammation, it is possible to fix the oscillating inner cone; that is, to prevent its re-ascent. It is also possible to effect this by narrowing the bore of the glass tube at one point, so as to diminish the rate of inflammation, i.e., to prevent the descent of the inner cone past that point. In this way it is possible to separate the two hollow cones of combustion which constitute the Bunsen flame, and to keep them any distance apart for any length of time. This permits of the aspiration of the gases from the space between the cones without any chance of admixture of outside air or of products of combustion from the upper cone.

The apparatus used by the authors in most of their experiments consisted of two glass tubes, one of which slides very easily within the other. The inner tube *c*, which is the longer one, is united to the outer one by an india-rubber collar *a*, through which it slides freely, and the two tubes are kept co-axial by a ring of asbestos packing *b*. The projecting end of the inner tube may be

fitted to a Bunsen burner, but the authors have usually led separate supplies of gas and air into the apparatus by a T-tube, instead of using a Bunsen burner, in order to have a better control of the flame. With this apparatus a non-luminous flame is easily obtained, and the two cones can be separated in two ways. If the apparatus is arranged so that the flame is formed at the orifice of the wider tube *d* and the orifice of the narrower one *c* is 8 or 10 cm. below it, on increasing the air supply the inner cone of flame will ultimately descend and rest upon the orifice of the inner tube. If, on the other hand, the inner tube be made to project beyond the outer one and the non-luminous flame be formed on it, then, if there be a sufficient air supply, on sliding up the outer tube it will as it passes the flame cleanly detach and carry up the outer cone, leaving the inner one still burning on the inner tube.

The authors have made similar experiments with flames of liquid hydrocarbons by charging air with the vapour of the liquid by passing it through a "saturator" such as is used for producing the ether-oxygen lime-light. The vapour-charged air is afterwards mixed with more air, and by suitably regulating the proportions a non-luminous flame is obtained and divided into two cones. In the case of liquid hydrocarbons, the lower cone of flame usually appears to be divided by dark spaces into several petal-like divisions which are in rapid rotation. In the case of benzene vapour the following sequence of appearances is presented: starting

with the orifice of the inner tube, 8 or 10 cm. below that of the outer one, a luminous smoky flame is first obtained at the latter; as air is gradually added the flame becomes less and less luminous, and an inner cone begins to develop, but before this has become non-luminous it descends to the inner tube; more air makes both it and the upper cone non-luminous, and this state may be maintained. If now somewhat less air is supplied, a luminous streak appears at the tip of the inner cone, and passes right up and through the tip of the upper cone. If more air is supplied, the upper cone of flame begins to disappear, and only the upper part of it remains; this also gradually fades away, and then there is only the lower cone left. Still more air produces a visible effect on the inner cone, the colour changing and the combustion becoming less intense until the cone rises from its seat, passes upwards, and disappears. There is thus a gradual transition from the richly luminous flame to one consisting of a simple pale-blue cone just on the point of extinction through excess of air.

The hydrocarbons examined by the authors were ethylene, methane, pentane, heptane, and benzene. Coal-gas was also used. The gases from the regions between the two cones of flame were analysed in all these cases volumetrically or gravimetrically.

The results obtained in the preliminary survey show that the products of combustion of the first cone are essentially CO , H_2O , CO_2 and H_2 , and that the second zone is due to the combustion of the CO and H_2 with the external air.

The results are in harmony with the conclusions of Blochmann, obtained indirectly, and with the not generally known work of Dalton on the explosion of methane and ethylene with oxygen in quantities insufficient for complete combustion, which was repeated in 1861 by Kersten.

The authors point out (1) that carbon, according to Baker's experiments, even in excess of oxygen, burns preferentially to CO , and not to CO_2 ; (2) that the heat of combustion of gaseous carbon to CO is probably greater than that of hydrogen to H_2O ; (3) that, according to Dalton, CH_4 when burnt with its own volume of oxygen, gives products represented in the equation—

and they conclude that this equation represents the character of the change first taking place in the inner cone. But as the two substances CO and H_2O act upon one another ($\text{CO} + \text{H}_2\text{O} \rightleftharpoons \text{CO}_2 + \text{H}_2$), the case is one of reversible change, and four products will result, viz., CO_2 , H_2O , CO , and H_2 .

The conditions of equilibrium of this system, according to Dixon, are expressed by the coefficient

$$\frac{\text{CO} \cdot \text{H}_2\text{O}}{\text{CO}_2 \cdot \text{H}_2} = 4.0.$$

This is subject to certain conditions of temperature and dilution. The authors in their most reliable experiments (viz., the gravimetric ones), with ethylene and coal-gas, get numbers not greatly differing from 4; but they are still engaged in studying this question.

The authors have succeeded in dividing into two cones flames produced by admixture of air with cyanogen, sulphuretted hydrogen, carbon bisulphide and decomposed ammonia (i.e., $\text{N}_2 + 3\text{H}_2$). The products of the inner cone in the case of cyanogen were found in one experiment to consist of CO and CO_2 in the proportion of 2 vols. of the former to 1 vol. of the latter.

Professor Smithells is continuing the experiments, with a view of elucidating the following points:—

- (i.) The influence of differences of diameter of the tubes and rates of efflux on the fractional combustion.
- (ii.) The exact composition of the interconal gases in the case of hydrocarbons, and also of mixtures of $\text{CO} + \text{H}_2$, so as to ascertain it, and in what way, the coefficient $\left(\frac{\text{CO} \cdot \text{H}_2\text{O}}{\text{CO}_2 \cdot \text{H}_2} \right)$ varies with the composition of the gases and other conditions.
- (iii.) The composition of the interconal gases from hydrocarbon flames whilst carbon is being liberated, so as to ascertain whether the luminosity of flames is due to simple decomposition of hydrocarbons by heat, to preferential combustion of hydrogen, to partial decomposition, or to other change.

- (iv.) The exact nature of the flame of cyanogen, so as to ascertain what governs the proportions of CO and CO_2 formed in the inner cone.
- (v.) The manner in which the partition of oxygen takes place in the inner cone between C and H, H and S, C and S, so as to obtain information as to the affinities of C, H and S for oxygen.
- (vi.) The spectroscopic appearances of the flames.

Note on the Structure of Luminous Flames. A. Smithells. Proc. Chem. Soc. 1891, 164--165.

THE author gives a brief summary of the various views that have been held on this subject. With one or two exceptions, there has been general agreement since the time of Berzelius that an ordinary candle flame, or the flame of coal-gas escaping from a circular hole, is divisible into four chief regions: (i.) the dark inner part; (ii.) the luminous part; (iii.) a small, bright blue part at the base of the flame, thinning off rapidly as it extends upwards; (iv.) a dim, scarcely visible, faintly luminous mantle surrounding the whole flame.

The explanation which the author would give of these regions is as follows:—The gas or vaporized wax, on issuing from the orifice or wick, becomes mixed with air and burns. Whether or not the flame is luminous depends on the rate at which the combustible is supplied. If slowly supplied, sufficient air is admixed with the gas for non-luminous combustion. Thus a very small gas flame is non-luminous, and so also the flame of a candle, with the wick cropped close to the wax. It is conventionally said that coal-gas burns with a luminous flame; it is just as true to say that it burns with a non-luminous flame. The small, non-luminous flame of coal-gas, or of a short wick candle, is seen to have the same structure as a Bunsen burner, viz., a bright blue inner cone, and a pale lilac cone superposed upon it. The author supposes that we have here the same chemical changes occurring as are dealt with in the previous paper, viz., that the first combustion in the inner cone is mainly to CO_2 , H_2O , CO and H_2 , and the final one in the outer cone is mainly that of CO and H_2 to CO_2 and H_2O . This is made more probable by the fact that if the gas supply be increased, the luminous tip appears just at the point where it appears in the experiment with benzene, and that even after it is considerably developed the shape of the flame betrays the persistence of the inner cone. As the gas supply is further increased, the luminous area becomes increasingly great, the relics of the two original cones being very small.

The author's view is further enforced by the simple experiment of taking a flame about 5 cm. high from a Bunsen burner with the air holes stopped, noting the blue region at the base of the flame and the dim mantle outside it and then gradually turning on the air. The gradual transition shows unmistakably that the blue part and the mantle are the "rudiments" of the two cones of a Bunsen flame.

With regard to the luminous part, everything goes to show that it is mainly a region where hydrocarbons are decomposed by the heat of the outer parts of the flame. The precise nature of the change is being studied by the author.

The dark inner zone contains mainly unburned gas, mixed with some products of combustion from surrounding regions.

A commonly held view that the mantle of a luminous flame is due to heated air and products of combustion is inconsistent with the above explanation, and also with the fact that in recent experiments it has been found impossible to render air luminous at the highest attainable temperatures.

The view that carbon is separated in a flame owing to the preferential combination of oxygen with hydrogen, is opposed, the author thinks, to all experimental evidence, which he is of opinion goes to show that if the oxygen supply be limited carbon will burn *before* hydrogen.

The author would describe a luminous flame as follows:—(i.) An outer sheath or mantle, with (ii.) an inner bright blue portion visible at the base of the flame. These

two parts correspond respectively to the outer and inner flame cones of a Bunsen flame, and mark the region where the coal-gas or candle-gas is burning with a large quantity of air.

(iii.) The yellow luminous part marking the region where the heat of the parts (i.) and (ii.) is decomposing hydrocarbons, setting free carbon, which rapidly glows and burns.

(iv.) The dark inner region, consisting of unburned gas, mixed with products of combustion of surrounding parts.

Novelty is not claimed for this description, but the author considers that the experiments described in the preceding paper put the matter in a somewhat new light.

PATENTS.

Improvements in Apparatus for Charging and Drawing Gas Retorts. J. Ruscoe, Hyde. Eng. Pat. 14,720, September 17, 1890. 11d.

THIS specification relates to a modified form of the apparatus described in Eng. Pat. 18,108 of 1889 (this Journal, 1891, 128), in which the latter is adapted to work in conjunction with the moveable division plate for charging inclined retorts, described by Trewby (Eng. Pat. 19,256 of 1889), and is also rendered capable of charging or drawing inclined retorts by means of an ordinary scoop or rack. There is in addition, on the top of the travelling framework on which the division plate or scoop is mounted, a coal-tank carrying sufficient coal to charge all the retorts in a row, and communicating by a sliding door with a measuring hopper which contains the quantity requisite for one charge, and is connected with a shoot delivering the coal at the mouth of the retort.

The mechanical details of the invention are illustrated by six sheets of drawings.—S. B. A. A.

Improvements in the Revivification of Materials Employed for the Purification of Coal-Gas, and in the Treatment of the Residues. C. W. Jones, Milan, Italy. Eng. Pat. 14,906, September 20th, 1890. 6d.

ACCORDING to this invention, the exhausted material is watered and mixed with about 6 per cent. of quicklime. It is then placed in a heap, and "allowed to remain until the reaction is complete, which is noticeable by its change of colour." The lime has now transformed the sulphates and compounds of ferrie-cyanide into the corresponding calcium salts of lime, and the oxide of iron is re-formed, and may be washed free from the other compounds. The washwaters are first heated in a boiler closed by a syphon dipping into a vessel containing sulphuric acid, by which the ammonia is retained; the residual liquors are evaporated down, and the cyanides recovered. Drawings are also given in the specification of a suitable arrangement of lixiviating tanks and boilers.—S. B. A. A.

Improvements in Stoves or Apparatus for Generating or Burning Gas obtained from Petroleum or other like Liquids for Heating Purposes. J. Dheyne, Schaerbeck; V. de Nydprück and F. de la Hant, Brussels, Belgium. Eng. Pat. 16,576, October 18, 1890. 8d.

THE apparatus consists of an hermetically closed reservoir provided with a screw-stoppered opening for charging the petroleum, an air-pump for compressing the contents, a safety valve, and a long, narrow tube passing through the cover, and reaching almost to the bottom of the reservoir. This tube is prolonged outside the reservoir for some distance, and is then wound round a narrow chimney downwards, the end brought inside the chimney and connected with a regulating nozzle. The worm is arranged in the centre of an ordinary lamp with a circular wick, suitably supported on the top of the reservoir. The upper part of the worm-chimney is provided with a cap covered with wire gauze or perforated sheet metal. The combination of lamp and worm-chimney is enclosed in a cylindrical casing, perforated below and notched above for the reception of objects to be

heated. The reservoir being charged with petroleum and pressure applied, the hydrocarbon is forced up the vertical tube and into the worm heated by means of the circular wick lamp, where it is volatilised and discharged through the regulating nozzle into the chimney, at the top of which it is ignited.—S. B. A. A.

Improvements in Setting Inclined Carbonising or Gas Retorts. L. Van Vestrant, Southall. Eng. Pat. 17,201, October 28, 1890. 6d.

DURING the erection of the retort-setting, a core of any required section is affixed to the upper end of the retort so that it is continuous with the inside of the retort, slanting at first in the same direction, and then curving and rising vertically upwards to the top of the setting. This is built in with brickwork, so that when the core is removed, a channel is left through which the retort may be readily charged. The lower surface of the channel may be lined with an iron plate for some distance from the junction with the retort; a lid, &c., is similarly fitted to the mouth.—S. B. A. A.

Improvements in the Manufacture of Combustible Gas for Heating, Lighting, and Generation of Motive Power. H. Guyon and L. Métais, Paris, France. Eng. Pat. 18,360, November 14, 1890. 8d.

INSTEAD of damping coke, resulting from the carbonisation of coal, in the open air as is usually done, the patentees effect its extinction in a closed vessel by means of steam and water successively. The steam, acting on the incandescent fuel, gives rise to a gaseous mixture of hydrogen, carbonic oxide, carbon dioxide, &c., which can be mixed with the illuminating gas, or utilised for the production of steam, and for various other purposes. When the coke has been cooled to a certain extent, water is injected into the vessel; the steam obtained in this way can be used as a motive power, or can be employed for damping the coke in the first stage of the process.

The residual coke can be sold at the same price as if it had been damped in the usual way. When, however, the coke is of low quality, it may be advantageously left in the closed vessel and raised to incandescence by injecting a stream of air; in the latter case it is damped again with steam and water successively, and the process continued until the coke is exhausted. For details of the vessel in which these operations are carried out, the specification and drawings must be consulted.—F. S. K.

A Manufacture of Porous Magnesian Bricks for the Linings of Stoves, Furnaces, Fireplaces, and Flues, and the Construction of Stoves and Furnaces with such Bricks. O. Clausen, Paris, France. Eng. Pat. 20,955, December 23, 1890. 8d.

THE patentee claims a system of stove construction, by which it is alleged the combustion of the fuel is more perfect than in existing arrangements, while the temperature of the products of combustion is but little above that of the surrounding air. For the attainment of these results he uses a form of stove made of porous magnesian bricks in which the combustion chamber is closed at the top, so that the first imperfect products of combustion are forced to pass downwards through the burning fuel, and come in contact with the air entering by a series of small holes surrounding the base of the chamber. In order to avoid excess of air a feeble draught is used, its precise amount being regulated by a valve at the front of the stove, or by plugs in the holes surrounding its base. The products of combustion pass up an annular space surrounding the combustion chamber, and then downwards close to the external wall of the stove, and finally away by a flue starting at its lower part. The magnesian bricks, to which the efficiency of the apparatus is said to be largely due, are formed by plunging bricks of a porous material into water containing magnesia in suspension. When used for heating rooms, the walls of the smoke flues may be covered with thin asbestos millboard,

with the view of transmitting and radiating the heat given off by them. The system is said to be applicable not only to domestic stoves, but to boilers and metallurgical furnaces.—B. B.

Improvements in the Manufacture of Illuminating Gas.
J. F. Allen, New York, U.S.A. Eng. Pat. 9716, June 9, 1891. 8d.

According to this invention, coal is distilled in a cupola furnace without access of air, and the gas is led through one of a pair of regenerative chambers situated under the cupola, then through the furnace fire employed to heat the regenerative chamber, and finally back to the bottom of the cupola and through the mass of glowing fuel in the interior. This circulation of the crude gas is continued until "a portion of the heat taken up by the crude gas in the regenerative chamber is transferred to the distillation chamber," and until "the water and tarry matters in the crude gas are decomposed."

One of the essential features which distinguish this process from others hitherto used is, "that the necessary heat for the destructive distillation of the carbonaceous material is created in and transferred from another chamber, and is not generated in the distillation."

For details the specification must be consulted.

—S. B. A. A.

Improved Means for Rendering Petroleum or other Liquid Hydrocarbons Non-explosive. S. Kirsch, Hamburg, Germany. Eng. Pat. 12,039, July 15, 1891. 1d.

It is claimed that petroleum oil may be rendered non-explosive by the addition of "small but sufficient quantities" of a mixture constituted as follows:—

	Per Cent.
Ambine.....	0.30
Sulphate of lime.....	0.92
Sulphate of magnesia.....	0.22
Bicarbonate of sodium.....	2.77
Chloride of sodium.....	92.3
Sal ammoniac.....	1.83
Water.....	1.14

The illuminating power of the petroleum is alleged not to be impaired by the addition.—S. B. A. A.

Improvements in the Manufacture of Illuminating Gas.
P. Dyckowicz, London. Eng. Pat. 13,506, August 10, 1891. 8d.

The apparatus described in this patent is employed for the continuous production of illuminating gas from steam and hydrocarbon oils; and its construction is such that the temperature of working varies only slightly, and consequently both the quantity and the quality of the gas produced are more constant.

A system of superheaters, in which air and steam are separately heated, and an oil gasifier are arranged in one and the same furnace setting; the air and steam superheaters are in connection with a pair of generators filled with coke. Hot air is blown into one of the generators until the fuel is raised to a suitable temperature, and then superheated steam is forced in; the water-gas formed in this way is mixed with superheated hydrocarbon vapour, and the gaseous mixture passed through condensers and scrubbers. The generator-gas formed in the first stage of the process is employed for heating carburettors, in which the oil vapour from the gasifier is mixed with the water-gas. The two generators are worked alternately, so that the process is continuous. There are four claims and two sheets of drawings.—F. S. K.

Improvements relating to the Manufacture of Ammonia and Gas. W. R. Lake, London. From A. Henmin, Springfield, U.S.A. Eng. Pat. 15,249, September 8, 1891. 8d.

The object of this invention is to generate gas and ammonia, simultaneously and continuously, from bituminous coal, shale or other fuel; this is done by forcing air and steam, or oxygen and steam, into a mass of incandescent fuel by means of radial tuyers arranged just above the grate of a generator of suitable form. The temperature at this part of the generator is high enough to bring about the complete decomposition of the steam employed, and also to convert the carbon dioxide into carbon monoxide. In the upper part of the generator the fuel is maintained at a much lower temperature, and is gradually carbonised as it passes downwards, the ammonia and other volatile products, together with the generator gas being drawn off near the top of the generator, and then treated in the usual way.

The greatest care must be taken to regulate the temperature of the various zones of the generator in order to prevent the decomposition of the ammonia.

With very crude and imperfect means of separating the ammonia from the gas, a quantity equivalent to about half the nitrogen in the coal has been obtained; the gas produced at the same time having the following composition:—

CO ₂	6.5
CO	29.0
CH ₄	2.25
H	43.0

This gas is practically free from undecomposed steam, and can be advantageously used for heating and metallurgical purposes. The make of gas per ton of fuel is said to be greater than that obtained by any process of like nature now known.—F. S. K.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

On the Formation of Acid Compounds in Petroleum.
R. Zoloziecki. Zeits. f. angew. Chem. 1891, 416—419.

The amount of acid substances contained in the various refined products from petroleum is very small, but from their behaviour towards the two indicators Methyl orange and phenolphthalein, they may be divided into two classes. The larger portion, neutral to the former, consists of lacto-alcohols, of distinctly marked acid character, which form mono-basic salts not only with the alkalis, but also with the oxides of the heavy metals, mixed with the ordinary fatty acids. The remainder, acid to methyl orange, is made up of acids containing sulphur. The oils were examined by treating in a dry separating funnel 100 cc. of the oil with 20 cc. of decinormal caustic soda and shaking vigorously several times. After thorough settling the soda was drawn off, filtered through a dry paper, and titrated back with acid.

To test the effect of exposure to air, some samples of oil were placed in a flask and a current of air passed through them by means of a pump, firstly at ordinary temperatures and afterwards hot, and finally several of the purified products were redistilled in a current of air or oxygen. In the distilled products were found amounts of acid corresponding to from 0.8 to 4.4 cc. of decinormal caustic soda per 100 cc. of oil, and, after exposure to air at ordinary temperatures for 12—24 hours, the average was only slightly higher, the results of the hot treatment being tabulated:—

	Cc. of decinormal acid required to neutralise 5 cc. of the Oil after previous addition of Caustic Soda.	
	Phenolphthalein.	Methyl Orange.
Intermediate oil, heated to 120°–130° in air for five hours.	3.60	4.8
Heavy oil, heated to 150°–160° in air for six hours.	3.20	4.6
Intermediate oil, refined, (Distillate distilled in oxygen up to 300° Residue.	1.4*	0.8
	1.5*	..
Intermediate oil (crude) distilled in oxygen.	2.0*	2.2
Heavy oil, distilled in air.....	2.6	3.4

* 10 cc. of caustic soda used.

On heating the heavy oil to a temperature over 350° in oxygen an explosion took place. During the distillations in air, and especially in oxygen, considerable amounts of water were produced at the higher temperatures, which had an acid reaction, due partly to acetic acid, and the distillate had the characteristic smell of fatty acids. These acids are probably derived from the oxidation of the methyl group in the methane hydrocarbons to carboxyl, hence being in proportion to the water evolved, whilst the lacto-alcohols are formed from slight oxidation of the unsaturated compounds present. This is shown by the fact that a purified intermediate oil was almost unchanged by treatment with air at ordinary temperatures, whereas an oil which had been redistilled ten times and hence in all probability contained unsaturated compounds, became strongly acid.

The large amount of acidity shown on titrating some of the products with Methyl orange must be due to the presence of mineral acids, and seeing that some of the crude distillates give almost the same figures as the refined ones, this cannot be the acid used in purification, but must exist in the raw oil, probably in the form of mercaptans and sulphides. By exposure to a current of cold air in presence of caustic soda, the acidity of the oil increases more rapidly, one purified sample giving 10.4 cc. after 12 hours' blowing, and before only 0.4 cc.—F. H. L.

Acids of Low Carbon Percentage occurring in Petroleum from Baku: Hepta- and Octonaphthene-carboxylic Acids. O. Aschan. Ber. 24, 2710–2724. (Compare this Journal, 1890, 597, and 1891, 825.)

Pure heptanaphthene-carboxylic Acid, prepared in a manner similar to that given in the first paper for the lower homologue, is a colourless, viscid oil, the smell of which much resembles that of the fatty acids. Its specific gravity at 0° is 0.9982. It is a strong acid, gradually decomposing calcium chloride, and is isomeric with the synthetical methylhexamethylenecarboxylic acid (1:2), boiling at 235°–236°, recently prepared by W. H. Perkin, jun., and Freer. Its boiling point is 237°–239°. The following compounds have been prepared:—The methyl ester boils at 190°–192°; its specific gravity at 18° being 0.9357, and its smell being pleasant but ultimately causing nausea. The potassium, sodium, calcium, barium, silver salts were also prepared, and it seems to be characteristic of the calcium salts of all the acids of the naphthene series, that they are more soluble in cold than in hot water.

By acting on the acid with phosphorus and hydriodic acid, the author has succeeded in preparing *octonaphthene*, identical in all respects with that isolated by Markownikow from Caucasian petroleum. Four grms. of heptanaphthene-carboxylic acid were heated with 0.4 gm. of red phosphorus and 3 cc. of hydriodic acid (sp. gr. 1.7) in a sealed tube for four hours to 200°–210°: after cooling, the end was broken off, and another 0.4 gm. of phosphorus introduced, the tube sealed up and heated to 220° for four hours, this operation being repeated twice again, 0.4–0.5 cc. of water

being added the last time, and the temperature finally raised to 240°. After the final heating, the resulting liquid product was removed with a pipette, washed with caustic soda, and digested in the warm with sodium. On distillation over a fresh amount of sodium, the principal portion passed over at 115°–119°, and another much smaller fraction at 240°–260°. The first of these was repeatedly distilled, and finally a product boiling at 117°–118° (742 mm.) was obtained, which formed about half the total amount of the crude hydrocarbons. On analysis it gave figures closely corresponding with the formula $C_{18}H_{12}$. Concentrated sulphuric acid was found to have no action on it, even in the warm, but it was easily dissolved by an excess of the fuming acid. Bromine was without action on it, and nitric acid only attacked it in presence of concentrated sulphuric acid. Its specific gravity at 0° was 0.7706, Markownikow's product being 0.7714, and boiling at 119°. Additional proof of the identity of these substances is found in the fact that the author has succeeded in preparing trinitrometaxylol (melting point 179°–180°) from his product, just as Markownikow has also prepared it from the naturally-occurring substance by the action of fuming nitro-sulphuric acid.

Octonaphthene-carboxylic Acid boils at 251°–253°; its specific gravity at 0° is 0.9893, and it resembles the lower homologue in every respect. The calcium and barium salts are not decomposed by carbonic acid. By evaporation on the water-bath, the latter is obtained in colourless, sticky lumps, which do not solidify on cooling; only by drying at 100° does it become hard and crystalline, it being then almost insoluble in cold water. The methyl ester boils at 211°–213°, and its specific gravity at 18.4 is 0.9352. The chloride boils at 206°–208°, and the amide melts at 128°–129°.

The author considers that the views expressed by Zaloziecki (Ber. 24, 1808; this Journal, 1891, 825) as to the nature of the acids examined by him, are unjustified. His acids are evidently also naphthene acids. The ease with which the various compounds described above are prepared from one another, their strongly characteristic properties, and their stability, show that these acids must contain a carboxylic group, and although, in the higher homologues, these properties are less strongly marked, as might be expected from analogy, there is absolutely no reason to believe that they are differently constituted (see preceding abstract).—F. H. L.

Petroleum at Baku. Journal de la Chambre de Commerce de Constantinople, November 14, 1891.

HOWEVER the exhaustion of the supplies of naphtha on the coast of the Caspian Sea may be questioned, the production of petroleum is increasing yearly.

According to data published by the *Karkaz* there were extracted 205,500,000 pounds in 1889 and 239,000,000 in 1890, which constitutes an increase of 16.3 per cent. The same progress is observed this year. Comparing the yield of the first half of 1891 with that of 1890, 12 months previously, the production of the six months was 126,000,000 pounds (poud = 36 lb. avoirdupois), whilst that for the first half of this year was 190,000,000 pounds, of which 171,000,000 are put down to the Balakhano-Sabountchi district, 13,000,000 to the Bibi-Eybate district, and 6,000,000 to that of Romany. The number of wells in working since the 1st January has increased from 273 to 335 at Balakhano-Sabountchi, from 3 to 13 at Romany, and at Bibi-Eybate they have remained unchanged at 14.

Included in this number of wells in August there were six springs at Balakhano-Sabountchi, four at Bibi-Eybate, and two at Romany.

The average depth of the bored wells in working is 96 sagènes (sagène = 7 ft.) at Balakhano-Sabountchi, 120 at Bibi-Eybate, and 103 at Romany. As regards the average production of naphtha every 24 hours, only including the ordinary bored wells and not the springs, it reaches 2,863 pouds at Balakhano-Sabountchi, 4,007 pouds at Romany, and 5,616 pouds at Bibi-Eybate.

Since the 1st January of the present year new borings have been made, having the following depths: At Balak-

hano-Sabountchi, 11,565 sâgènes; at Bibi-Eybate, 690; and at Romany, 1,482.

It should be observed that the district of Romany has not realised the brilliant anticipations held at the time of the discovery of naphtha in that locality a year ago. Naphtha is only found there at a very great depth, which increases the cost of working.

The Arafeloz naphtha spring again commenced to run, but only for eight hours, and it has given in this space of time 20,000 pounds of naphtha to its owner; then it stopped again. But as it is hoped that the spring will once again operate, three enormous basins for storing the naphtha which it will give have been prepared.

PATENT.

Improved Means for rendering Petroleum or other Liquid Hydrocarbons Non-explosive. S. Kirsch, Hamburg, Germany. Eng. Pat. 12,039, July 15, 1891. 4d.

See under II., page 996.

IV.—COLOURING MATTERS AND DYES.

Orthoquinolinehydrazine. S. F. Dufton. J. Chem. Soc. (Trans.) 1891, 756—759.

ORTHAMIDOQUINOLINE is diazotised in the usual way, the calculated quantity of stannous chloride dissolved in strong hydrochloric acid is added, and the tin compound obtained is decomposed by hydrogen sulphide. The hydrazine dihydrochloride thus obtained crystallises in thick yellow lustrous prisms. Its formula is—

The free hydrazine forms fine, long, slightly yellow needles melting at 64°.

Orthoquinoline semicarbazide, $\text{C}_6\text{H}_4\text{NH}_2\text{NH}_2\text{CONH}_2$, is obtained on mixing aqueous solutions of potassium cyanate and of the above hydrazine hydrochloride. It crystallises from hot alcohol in white shining leaflets which melt at 235° with decomposition.

On the addition of pyruvic acid to a strong aqueous solution of the hydrazine hydrochloride, the *hydrochloride of the pyruvic acid hydrazine* is produced. It crystallises from water in beautiful orange needles. The free hydrazine—

melts at 174° and possesses both acid and basic properties.

When the pyruvic acid compound of quinolinehydrazine is heated with hydrochloric acid, *orthoquinindole- α -carboxylic acid*—

is obtained. It crystallises in slender columnless needles melting at 286° with decomposition.—A. K. M.

Diazo- and Hydrazine Compounds of the Quinoline Bases. E. Böttiger. Ber. 24, 1891, 3276—3277.

THE author refers to Dufton's paper on "orthoquinoline-hydrazine" (see previous abstract), and states that before the publication of the latter, he had already applied for a patent for the preparation of quinolinehydrazines.

Diazoquinoline chloride, which is not described by Dufton, is formed when sodium nitrite solution is added to a well-cooled solution of orthamidoquinoline in hydrochloric acid. It is not decomposed by boiling with acids, but evolves nitrogen when heated with alkali. It yields azo colours which will dye wool directly but not cotton.

Orthoquinolinehydrazine yields a well-crystallised sulphate and hydrochloride, both of which dissolve readily in alcohol, ether, and in water. The hydrazine melts at 64°, reduces Fehling's solution in the cold, and yields characteristic hydrazones with ketones and aldehydes.—A. K. M.

A New Class of Fluorescent Dyes of the Quinoxaline group II. O. Fischer and M. Busch. Ber. 24, 1870—1871.

THE authors have previously described (this Journal, 1891, 535) the formation of dihydroquinoxalines from α -keto-alcohols and unsubstituted or mono-N-substituted orthdiamines of the benzene group, and called attention to the bright colours obtained and the fluorescent properties of these products. The compounds obtained from unsubstituted diamines contain no oxygen and are readily converted by oxidation into quinoxalines; the substances formed from benzoïn and orthamido-*p*-ditotylamine or phenyl β -naphthalenediamine are likewise free from oxygen and give rise to a series of unstable salts. None of these derivatives can therefore be identical with Witt's oxidised azonium bases (Ber. 24, 1511; this Journal, 1891, 827).

When 1:2:3-triphenyl-1:2:hydronaphthoquinoxaline, the product of the condensation of benzoïn and β -phenylortho-naphthalenediamine is treated with ferric chloride, it is converted into an iron derivative of the corresponding azonium base—

The free base crystallises from alcohol in yellow lustrous prisms with a bright green reflex; these lose lustre and turn brown at 110°, soften at 162°, and melt at 167°. The body is insoluble in water but dissolves readily in ether and benzene, and with some difficulty in alcohol, forming yellowish-green fluorescent solutions. The alcoholic solution turns to a clear yellow colour on addition of hydrochloric acid. It forms stable salts the neutral aqueous solutions of which exhibit a strong yellowish-green fluorescence which disappears on addition of mineral acids. The *nitrate* forms a yellow crystalline powder difficultly soluble in water, the *chloride* crystallises from dilute alcohol in large dark yellow needles. The azonium bases may be directly formed from benzoïn, and in this case β -phenyl-*o*-naphthylenediamine, by heating them with zinc chloride at 200°, the zinc chloride acting like the acids in promoting the oxidation of any hydro-derivative formed. Of course for other azonium bases other and corresponding diamines must be taken instead of β -phenyl-*o*-naphthylenediamine. 1:3-diphenylethonaphthazonium bromide prepared by boiling a dilute alcoholic solution of bromacetophenone and β -phenolnaphthylenediamine in molecular proportions, crystallises in lustrous yellow plates, and exhibits an intense yellowish-green fluorescence when dissolved in dilute alcohol. The corresponding base 1:3-diphenylethonaphthazonium hydrochloride—

prepared by the action of soda on the bromide, crystallises from absolute alcohol in lustrous transparent pale green prisms which turn brown at 100°, melt at 148°, dissolve

readily in ether, hot benzene, and glacial acetic acid, with difficulty in alcohol and light petroleum, and not at all in water. The alcoholic, and more especially the glacial acetic acid solutions, are highly fluorescent, the others less so. The *nitrate* crystallises in yellow silky lustrous needles difficultly soluble in water.—S. B. A. A.

Azonium Bases. F. Kehrman and J. Messinger.
Ber. 24, 1871—1876.

On heating phenyl-*o*-phenylenediamine (5 grms.) with benzoïn (6 grms.) for 10 hours at 170°—180°, the product, after purification by O. Fischer's method, separates from 90 per cent. alcohol in yellowish-green fluorescent crystals, which melt at 116°—117° with previous softening, and dissolve readily in ether, benzene, and hot alcohol, but not in water or dilute mineral acids. All the solutions exhibit a magnificent bluish-green fluorescence; the alcoholic solution turns deep blood-red on addition of acids. It forms blood-red salts, which undergo complete dissociation on treatment with water. These reactions show that the base described is not identical with that obtained by the authors from benzile and phenylorthophenylenediamine (Ber. 24, 1239), but more nearly resembles the indulones (Ber. 24, 584; this Journal, 1891, 757). The relations between these compounds are shown by the following formulae:—

Azonium base from benzile and phenylorthophenylenediamine—

Quinoxaline base from benzoïn and phenylorthophenylenediamine—

Indulone from oxyquinone and phenylphenylenediamine.
—S. B. A. A.

Tetrahydro-orthamidoquinaldine. E. Bamberger and P. Wulz. Ber. 24, 2049—2055.

THE authors have prepared tetrahydro-orthamidoquinaldine and investigated its reactions more especially with the object of testing the applicability of Bamberger's "theory of hydrogenation" to the entire quinoxaline series. According to the theory, tetrahydro-orthamidoquinaldine should behave like an alkyl-substituted orthophenylenediamine, and the following results show that such behaviour does actually take place:—

Tetrahydro-orthamidoquinaldine—

is prepared by repeatedly boiling orthamidoquinaldine with excess of tin and hydrochloric acid, collecting the deposit of tin double salts, which separate from the solution on cooling, triturating with soda, and extracting the resulting emulsion with chloroform. On adding an acid solution of ferric chloride or potassium bichromate, it immediately yields the intense red colouration characteristic of orthodiamines.

α-Methyltetrahydro-periquinaldimidazole—

This is an anhydro-base or imidazole formed on boiling the preceding compound with glacial acetic acid, sodium acetate,

and a few drops of acetic anhydride. It crystallises from ether in large flat prisms with an adamantine lustre, dissolves in alcohol, chloroform, and hot water, and melts at 110°. It is a very powerful and stable base, dissolves readily in acids, and possesses the general characteristics of an imidazole. It gives no colouration with ferric chloride or potassium bichromate.

The *platinochloride* crystallises in lustrous orange-coloured prisms, soluble in hot water. The methyl group in the methylated imidazoles of the benzene series, like the corresponding group in quinaldines, readily undergoes condensation. By melting the preceding imidazole with phthalic anhydride, a deeply coloured *phthalone* of the composition—

is formed. This colouring matter is obtained in ill-defined yellow crystals, and dissolves readily in boiling glacial acetic acid and in concentrated sulphuric acid, forming orange-coloured solutions from which the phthalone is precipitated on addition of water. On heating it sublimes in slender lustrous needles. It generally resembles the quinoxalines in its behaviour towards reagents, in colour, &c.

It is improbable that the condensation occurs between the methyl group of the quinaldine nucleus and phthalic anhydride, since on heating tetrahydroquinaldine with phthalic anhydride the product is not a phthalone, but probably has the composition—

—S. B. A. A.

Homologues of Tetrahydroquinoline. E. Bamberger and P. Wulz. Ber. 24, 2055—2076.

Communication No. IV.—Hydrogenised Quinolines.

Tetrahydro- α -methylquinoline—

is prepared by reducing orthomethylquinoline with granulated tin and hydrochloric acid, decomposing the tin double salt formed with aqueous sodium hydrate, and extracting the distillate with ether. The operation is repeated upon the partially reduced product so obtained. The pure base is a colourless pungent-smelling oil which boils at 255°—257° under 717 mm. pressure, does not solidify in a freezing mixture, dissolves readily in organic solvents, and with some difficulty in water. It is quickly turned yellow by atmospheric oxygen. The *hydrochloride*, $\text{C}_{10}\text{H}_{13}\text{N} \cdot \text{HCl}$, crystallises from alcohol in highly refractive monoclinic plates, melts at 214°, dissolves readily in water and hot alcohol or chloroform, but is insoluble in benzene, ether, and light petroleum. In acid solutions potassium dichromate and ferric chloride produce a brownish-yellow colouration changing to dark brownish-green and olive green respectively. The *acetyl derivative*, $\text{C}_{10}\text{H}_{12}\text{N} \cdot \text{COCH}_3$, crystallises in prisms, melts at 53°—54°, boils at 297°—299° under 718 mm. pressure, and dissolves readily in alcohol, benzene, &c. The moist crystals turn blue on exposure to the air. The *nitroso derivative*, $\text{C}_{10}\text{H}_{12}\text{N}(\text{NO})$, forms thin hexagonal plates or vitreous prisms, melts at 51°, and dissolves readily in organic solvents. The *diazo-amido derivative*—

is obtained in orange-coloured, oily drops on shaking a mixture of the chloride of the base (2 grms.) and sodium acetate (7 grms.) with the theoretical quantity of diazo-benzene chloride. It crystallises in very soluble, slender, yellow needles melting at 99°. The alcoholic solution is at once coloured violet-red by a trace of mineral acid, the isomeric azo-dye being formed. It is coloured red by fusion

with resorcinol, violet-red by glacial acetic acid and α -naphthylamine, and generally exhibits the typical reactions of a diazo-amido compound.

Tetrahydro- α -methylquinoline- p -azobenzenesulphonic acid, $C_9H_9CH_3.N_2.C_6H_4SO_3H$, is prepared by treating the hydrochloride of the base suspended in cold water with an equal quantity of para-diazobenzene-sulphonic acid. The yield is about 155 per cent. of the hydrochloride used. It strongly resembles the homologous colouring matter from tetrahydroquinoline, crystallises in brownish-violet glistening needles, and dissolves sparingly in hot water and in alcohol, forming orange-coloured and fuchsine-red solutions respectively; it is readily soluble in alkalis, and is re-precipitated from its solutions on addition of hydrochloric acid in tufts of dark violet needles with a metallic reflex. In an acid bath it dyes wool and silk orange-yellow, and exhibits the bad tinctorial properties of the tropaeolines in a high degree. The sodium salts form brick-red flakes, soon changing to thin plates with a green reflex.

Tetrahydro- α -methyl- p -amidoquinoline—

is prepared by reducing the azo dyestuff with tin and hydrochloric acid, decomposing the resulting tin salt with soda, and extracting with ether. The hydrochloride crystallises in monoclinic vitreous prisms, which do not solidify at 310°. The free base has the properties of a para-diamidobenzene, giving with hydrochloric acid, ferric chloride, and hydrogen sulphide a fine violet colouration (thionin), and with potassium dichromate and acetic acid an intense green changing to red on heating (indamine and safranine). An aqueous solution of the hydrochloride also yields with m -tolylmediamine chloride and potassium bichromate a deep blue colouration and precipitate changing to violet and red on heating (tolylene blue and red).

Tetrahydro- p -methylquinoline, $C_9H_9CH_3$, is prepared from p -methylquinoline like the α -compound. It crystallises in silvery prismatic tables, melts at 38°, boils at 262.3° under a pressure of 712 mm., dissolves readily in alcohol, chloroform, &c., but only sparingly in water. The hydrochloride, $C_9H_9CH_3.N.HCl$, crystallises in long silvery needles, melts at 189°, and dissolves readily in water, alcohol, and hot chloroform, but is insoluble in ether, benzene, and light petroleum. Ferric chloride colours the neutral solution deep reddish brown changing to olive-green, and the acid solution yellowish-brown; potassium dichromate and sulphuric acid give a dark brown to Bordeaux red colour, which gradually becomes greenish. The acetyl compound, $C_9H_9CH_3.CO$, is a colourless viscid oil boiling at 302—305° under a pressure of 719 mm.; the nitroso derivative, $C_9H_9CH_3.NO$, crystallises in thin, pale yellow, monoclinic tables or flat prisms, and melts at 65°; the diazo-amido compound, $C_9H_9CH_3.N_2.C_6H_5$, is prepared like the α -compound, and crystallises from alcohol in pale yellowish, flat, lustrous prisms melting at 74.5°, and readily soluble in organic solvents. Unlike the α -compound, it does not yield an isomeric azo-dyestuff on warming with acids, but splits up into phenol and tetrahydro- p -methylquinoline. It further resembles the diazo-amido compounds in giving the characteristic reactions with resorcinol, α -naphthylamine, and glacial acetic acid, &c.

Tetrahydro- p -methylquinoline- α -azobenzenesulphonic Acid, $C_9H_9CH_3.N_2.C_6H_4SO_3H$, is prepared by adding diazobenzene-sulphonic acid (3 grms.) suspended in water (100 grms.) to a well-cooled solution of the hydrochloride of the base (3 grms.) in water (40 grms.) acidified with fuming hydrochloric acid (2 cc.). The yield is only 122 per cent. of the hydrochloride used. This dyestuff forms a deep violet-black crystalline powder, insoluble in ether, but readily soluble in alcohol, and sparingly so in water. The aqueous solution is of a deep wine-red colour, changing to violet on addition of acid. It forms dark cherry-red solutions in concentrated sulphuric acid and in alkalis. In an acid bath it dyes wool and silk Bordeaux red. The sodium salt crystallises in Bordeaux red needles with a brownish-green metallic reflex.

α -amidotetrahydro- p -methylquinoline, $C_9H_9CH_3.NH_2$, is prepared by reducing a solution of the azo-dyestuff in

aqueous soda with zinc dust. The hydrochloride forms colourless prisms which decompose at 216°. The neutral solution is coloured deep Bordeaux red by ferric chloride or potassium bichromate like other orthodiamido compounds; on warming with a drop of nitric acid the same effect is produced, but the colour changes to yellow on cooling. The red colour is also obtained on addition of a small quantity of calcium chloride, and is changed to yellow by an excess. The alcoholic solution gives with sodium acetate and hydroxynaphthaquinone the intense red colouration characteristic of alkylated orthodiamidobenzenes, a rosindone being probably formed.

α -methyl- m -methyltetrahydroperiquinimidazole—

This is an anhydro-base or imidazole prepared by the action of acetic acid on the preceding compound. It crystallises in silky needles or flat prisms, melts at 163°, distills unchanged at 360°, sublimes in beautiful needles, dissolves readily in hot water, alcohol, chloroform, but only very sparingly in light petroleum. The picrate is a yellow sandy crystalline powder, the chromate forms tufts of yellow needles, the platinochloride crystallises in orange-coloured needles freely soluble in hot water, a phthalone dyestuff, $C_{19}H_{11}N_2.CH(C_6O_2.C_6H_5)$, is formed by the action of phthalic anhydride on the base; it crystallises from glacial acetic acid in golden yellow prisms which do not melt at 310°.

Benzenediazo-amidotetrahydro- p -methylquinoline Sulphonic Acid, $C_{10}H_{12}.N_2.C_6H_4SO_3H$, is formed together with the isomeric azo-dyestuff described even in presence of an excess of acid, the barium salt crystallises in glistening white plates. With resorcinol and α -naphthylamine, the characteristic red and violet colours of the respective sulphophenylazo-dyestuffs are obtained, in other respects it also behaves as a sulphonated diazo-amido compound.

Tetrahydro- α - p -dimethylquinoline, $C_9H_9(CH_3)_2$, prepared by the reduction of α - p -dimethylquinoline, is a colourless oil boiling at 272—273° under a pressure of 720 mm., the hydrochloride crystallises in rhombic prisms, and when pure melts at 272°. Ferric chloride produces in its neutral solution a yellowish to an emerald-green colouration which changes to yellow on warming. With potassium bichromate and sulphuric acid a brownish-green colouration is produced on warming. The acetyl derivative is a viscid colourless oil boiling at 313.5° under a pressure of 719 mm., the nitroso derivative crystallises from alcohol on dilution with water in thin lustrous plates and melts at 42°, the diazo-amido compound, $C_{11}H_{14}.N_2.C_6H_5$, crystallises in slender prisms and melts at 88—89°. On warming with mineral acids it breaks up into phenol and α - p -dimethylquinoline, with evolution of nitrogen.

From the above results it appears that tetrahydro- α -methylquinoline, tetrahydro- p -methylquinoline, and tetrahydro- α - p -dimethylquinoline respectively behave like an alkylated α -toluidine, p -toluidine, and asymmetrical xylidine (see following abstract).—S. B. A. A.

Methyl-para-toluidine. E. Hamberger and P. Wulz.

Ber. 24, 2077—2086.

It was previously shown (see previous abstract) that the action of p -diazobenzene-sulphonic acid on tetrahydro- p -methylquinoline results in the formation of a mixture of an azo-dyestuff, and an isomeric diazo-amido compound. Para-diazobenzene-sulphonic acid acts in a similar way on methyl-para-toluidine, the "monocyclic" analogue of tetrahydro- p -methylquinoline.

Formoparatoluidide—

An almost theoretical yield of this compound is obtained by boiling equal weights of paratoluidine and crystalline

formic acid at a low pressure (20–30 mm.), removing any unaltered toluidine, and heating for a short time to 250°.

Methylformoparatoluidide—

prepared by heating an alcoholic solution of formotoluidide (13.5 grms.) with methyl iodide (15 grms.), and strong alcoholic potash (5.6 grms.) crystallises in large prisms, which melt at 30°, and distils at 273°–277° with slight decomposition.

Methylparatoluidine—

is obtained in a state of purity by digesting the preceding compound with fuming hydrochloric acid. It distils at 207°–209° under a pressure of 715 mm., the *hydrochloride* crystallises in large prisms of vitreous appearance, melts at 119.5°, and dissolves readily in water and alcohol. In aqueous solution it is coloured reddish-brown by ferric chloride, and chestnut brown by potassium bichromate and sulphuric acid. The *nitroso* derivative—

crystallises from ether in brownish-yellow lustrous plates, and melts at 52°–53°.

Methylparatoluidine-o-azobenzenesulphonic acid—

prepared by adding diazobenzenesulphonic acid (2.3 grms.) suspended in water (150 grms.) to a well cooled solution of methyltoluidine chloride (2 grms.) in water (20 cc.), and dilute sulphuric acid (1 cc.). 5.5 grms. of the acid are obtained from 6 grms. of the chloride. It crystallises from boiling water in deep violet-black vitreous-looking prisms, melts at 198°–199°, and dissolves readily in most solvents; the aqueous solution is dark raspberry-red, the alcoholic solution dark wine-red, the sulphuric acid solution cherry-red. It dyes wool and silk a dark orange colour in an acid bath, the *sodium* salt forms deep red crystalline flakes, converted by prolonged standing under water into small iridescent plates.

o-amidomethyl-p-toluidine—

is prepared by reducing the preceding dyestuff with stannous chloride and hydrochloric acid. The *hydrochloride* crystallises when pure from alcohol in small colourless and vitreous-looking prisms, which begin to melt at 175°, and decompose at 180°–185°. The free base is obtained by hydrolysing the hydrochloride. It crystallises from ether in colourless prismatic tables, melting at 43°, and is identical with the compound prepared by Gattermann from nitromethyl-p-toluidine (Ber. 18, 1487). In acid solutions it is coloured deep red by oxidising agents, like other orthoamidido compounds.

α-β-dimethyl-m-dimethylbenzimidazole—

prepared by boiling the hydrochloride of the preceding base with sodium acetate and glacial acetic acid crystallises in lustrous needles and melts at 141.5° to 142°. It is identical with the anhydro-base or imidazole prepared by Niementowski from methylnitro-p-acetotoluidide.

Benzenediazo-amidomethyl-p-toluidine sulphonic acid—

The *sodium* salt is obtained by treating the filtrate from the azosulphonic acid with soda. When pure it forms white plates very sparingly soluble in alcohol or water; the aqueous solution gradually turns red on standing, and the isomeric azo-dyestuff is deposited. The *silver*, *lead*, *barium*, *cadmium*, and *cadmium* salts crystallise in needles, the *copper* salt forms a light green crystalline precipitate; the solutions of all these salts turn red on warming. This sulphonic derivative yields the colour reactions of diazoamido compounds with resorcinol and α-naphthylamine; on boiling with acids it splits up into methyltoluidine and phenol-sulphonic acid with evolution of nitrogen.—S. B. A. A.

Relations of the Eurhodines to the Indulines and Suframines. F. Kehrman, and J. Messinger. Ber. 24, 2167–2175.

Methylrosindulone—

is prepared by mixing saturated alcoholic solutions of hydroxynaphthaquinone and methyl-α-phenylenediamine in molecular proportions, and allowing it to stand for 3–4 hours. It crystallises from a mixture of alcohol and benzene in cinnamon-red needles with a metallic green reflex, melts at 257°–259°, and dissolves with some difficulty in alcohol, ether, and benzene, forming yellowish eosin-red solutions with a brick-red fluorescence. The *hydrochloride* crystallises in brown needles with a green reflex, and is decomposed by water. The concentrated sulphuric acid solution of methylrosindulone is dichroic, being greyish-green in thin and dark purple in deep layers, it becomes orange-coloured on dilution. A *bromo*-derivative is obtained by acidifying the alcoholic solution with hydrochloric acid, saturating with bromine water and adding excess of sulphurous acid. It crystallises in green needles, decomposes at 250° without melting, and dissolves sparingly in most organic solvents forming fuchsin-red solutions.

α-Naphtho-eurhodole dissolves in dilute aqueous soda, forming blood-red solutions; on addition of a concentrated solution of soda a *sodium* derivative is precipitated in gold coloured leaves with a metallic lustre strongly resembling the crystallised rosindulones. On heating α-naphtho-eurhodole suspended in methyl alcohol with soda and excess of methyl iodide and diluting the product with water an indistinctly crystalline red precipitate is thrown down consisting of a mixture of methylrosindulone and methoxy-naphthophenazine. These products are separated by dissolving in boiling alcohol, adding concentrated hydrochloric acid, and then carefully precipitating the azine with water; on adding ammonia to the filtrate methylrosindulone is precipitated. Methoxynaphthaphenazine crystallises from alcohol in pale yellow lustrous needles, melts at 176°–177°, and sublimes at a higher temperature. It is insoluble in alkalis, but dissolves in concentrated sulphuric acid, and is reprecipitated on dilution; it also dissolves in boiling alcohol, benzene, &c. It is not acted on by bromine water.

The preceding reaction provides a new method of synthetically preparing indulones from eurhodoles, and the authors consider that the formation of both methylrosindulone and methoxynaphthaphenazine from α-naphtho-eurhodole conclusively proves the tautomeric character of the latter compound, which may be regarded as alternating in constitution between an imidoquinone and a hydroxyazine (this Journal, 1891, 737).—S. B. A. A.

Bromisatine Blue and the Compounds of Mono- and Dibromisatine with Piperidine. C. Schotten. Ber. 1891, **24**, 2601—2607.

THE author recently showed that a blue colouring matter—Isatine-blue—is readily produced either by the action of heat alone or by the action of acid anhydrides on dipiperidylisatine (this Journal, 1890, 699).

Dipiperidylmonobromisatine, $C_{12}H_{16}BrNO_2 \cdot C_5H_{10}N_2$, obtained on heating an alcoholic solution of monobromisatine (1 mol.) with piperidine (2 mols.), forms colourless needles. When this is heated with acetic anhydride, *Bromisatine blue* is produced, the formula of which the author has not succeeded in establishing.

Dibromisatine and piperidine react in equimolecular proportions, yielding the *piperidide of dibromisatinic acid*—

This is sparingly soluble in alcohol, soluble with moderate ease in ether, and insoluble in water. It is not decomposed by boiling with dilute mineral acids, alkalis, glacial acetic acid, or acetic anhydride, but when it is heated with a mixture of glacial acetic acid and hydrochloric acid it becomes decomposed and apparently yields dibromisatine. It melts at 152° to a brown coloured liquid.—A. K. M.

Benzene-azo- α -Naphthylglycine. A. Donner. Ber. 1891, **24**, 2902—2904.

A SOLUTION of aniline in nine parts of dilute hydrochloric acid is diazotised and combined with a solution of α -naphthylglycine in dilute hydrochloric acid. After a short time the mixture is coloured intensely reddish blue, and after 12 hours' standing a considerable amount of a dark blue crystalline precipitate is formed. The body melts after purification at 170° C. with evolution of gas. The analysis proved it to be the hydrochloride of benzene-azo- α -naphthylglycine ($C_{12}H_{11}N : N : C_{10}H_7NHCH_2 \cdot CO_2H$) (HCl).

The compound is with difficulty soluble in water, more easily in concentrated hydrochloric acid, and abundantly in alcohol. All the solutions exhibit a reddish-blue colour, changing on addition of alkalis into a yellowish-red, concentrated sulphuric acid dissolves the compound with a deep blue colour, changing into violet on dilution. The hydrochloric acid solution of the body dyes silk a violet, its alkaline solution a golden yellow. The hydrochloride dissociates on washing with water, the melting point of the substance being lowered about 20° C. On treating the hydrochloride with the theoretical amount of potassium hydrate, evaporating to dryness and exhausting the residue with hot alcohol, crystals separate from the filtrate in the shape of small, bright, green needles, melting at 133° C. with evolution of gas. The author believes this compound to be represented by the formula—

A Synthesis of Wessely's Resorcinol Blue. R. Nietzki. Ber. 1891, **24**, 3366—3369.

THE constitution of resorcinol, C_6H_2NO , has been ascertained, whilst that of resorazurine is still doubtful. The author discovered a new synthesis of the latter compound. Equal molecules of mononitrosoreosinol and resorcinol are dissolved in 15 parts of cold alcohol and 1 mol. of finely divided manganese peroxide is suspended in this solution.

Two mols. of sulphuric acid diluted with the same volume of water are allowed to run gradually into the mixture, which has to be all the time well cooled. After some time the solution is coloured of a deep cherry red. As soon as a drop produces on filter-paper a pure blue spot without showing a yellowish green rim, the solution is separated from the manganese peroxide by filtration and then precipitated with water. On mixing the precipitate with a solution of carbonate of soda, which must not be too dilute, the sodium salt of resazurine separates in green crystals, whilst the mother-liquor contains an abundant quantity of the sodium salt of resorcinol. The author explains the reaction in the following equation—

On α , β -Amidonaphthalenesulphonic Acid and its Derivatives. P. T. Cleve. Ber. 1891, **24**, 3472—3477.

LASCHOFF and Meyer discovered that an amidonaphthalenesulphonic acid is obtained if the salts of naphthionic acid are heated to 200—256° C. This new acid is an α , β -derivative—

as the α , β -dichloronaphthalene melting at 34° C. can be obtained from it. The free acid crystallises in long needles, is soluble in 34 parts of boiling and 225 parts of cold water. It crystallises in two forms, either without water or with half a mol. of water. The author describes a number of salts further:

α , β -Acetylamidodisulphonic Acid—

obtained by heating the acid with acetic anhydride. It forms small needles, losing their water of crystallisation at 150° C. On treating the amidonaphthalenesulphonic acid with one mol. of sodium nitrite a diazo compound is obtained as a greenish precipitate which is converted by the action of stannous chloride into—

α , β -Hydrazinenaphthalenesulphonic Acid—

crystallising in plates.

α , β -Chloronaphthalenesulphonic, $C_{10}H_6ClSO_3H$, is prepared by treating the diazo compound with a solution of cuprous chloride in hydrochloric acid; and

α , β -Dichloronaphthalene, $C_{10}H_6Cl_2$, from the previously-mentioned compound in the usual way. It melts at 34° C.

On adding the diazonaphthalenesulphonic acid to boiling dilute sulphuric acid, a blue solution is obtained, yielding after purification—

α, β-Naphtholsulphonic Acid, C₁₀H₆(OH)SO₃H

Ferric chloride produces in its solution an indigo blue colour changing soon into a dirty red. The combination with diazotised naphthionic acid is of a magenta-red colour.—A. L.

On 1:6:4 Dichloronaphthalenesulphonic Acid. P. T. Cleve, Ber. 1891, **24**, 3477—3479.

On sulphonating 1:6 dichloronaphthalene with a mixture of equal volumes of fuming and ordinary sulphuric acid a sulphonic acid is obtained with difficulty soluble in dilute sulphuric acid. A great number of salts and other derivatives of this compound are described, amongst them—

1:4:6 *Trichloronaphthalene*, melting at 56° C. if cooled rapidly, at 65° C. if cooled slowly. This compound proves that the constitution of the dichloronaphthalenesulphonic acid is—

—A. L.

Hydroxy-Derivatives of Alizarin Blue. R. E. Schmidt and L. Gattermann. J. Prakt. Chem. 1891, **49**, 103—109.

THE authors have previously shown that by the action of strongly fuming sulphuric acid on anthraquinone and on its hydroxy-derivatives, a new class of colours, the *Alizarin Bordeaux* result. (This Journal, 1891, 537 and 759, and J. Prakt. Chem. 1891, **43**, 237 and 240.) Alizarin bordeaux is tetrahydroxy-anthraquinone and yields both a nitro- and an amido-derivative, from the latter of which the corresponding anthraquinoline compound can be prepared. This Dihydroxy-alizarin blue is almost insoluble in the usual reagents, but dissolves in nitrobenzene, which is the best solvent for the various members of this group of bodies. It separates from this solution in blue needles having a copper-like metallic lustre and closely resembling indigo in appearance. Concentrated sulphuric acid dissolves it with a bright greenish-blue colour, and this solution gives two sharp absorption bands in the spectrum, one in the red and one in the orange. When heated it yields a violet-coloured vapour resembling that of iodine. Analysis and the method of formation point to the following constitutional formula:—

Dihydroxyalazarin blue.

When alizarin blue itself is treated with fuming sulphuric acid in a similar manner to that in which Alizarin bordeaux is prepared from alizarin, the above compound does not result, but a Trihydroxy-alizarin blue C₁₇H₆NO₄(OH)₃ is formed, which closely resembles the dihydroxy-compound in physical properties.

The manufacture of colours of a somewhat similar nature (alizarin blue-green, alizarin green, and alizarin indigo-blue) has been patented by the Badische Soda und Anilin Fabrik. (Eng. Pat. 14,353 and 15,121 of 1888; this Journal, 1889, 770 and 772), but beyond a short note by Graebe (Ber. 1890, **23**, 3739) no work has been done on the nature of these colours. Graebe's experiments pointed to the colours being derived from a mono- or dihydroxy-alizarin blue. The result of

the authors' investigations is to show that the "*Alizarin blue-green*" is the mono-sulphonic acid of monohydroxy-alizarin blue. When heated with hydrochloric acid to 160—170° C. the sulphonic acid group is removed and monohydroxy-alizarin blue formed. This body crystallises from nitrobenzene in glittering copper-like plates, which dissolve in concentrated sulphuric acid with a violet colour. Like Alizarin blue its alkali salts are insoluble in an excess of alkali. "*Alizarin green*" is also a mono-hydroxy-alizarin blue monosulphonic acid, and therefore isomeric with Alizarin blue-green. It results, as stated in the patent, by the action of mono-hydrated sulphuric acid on Alizarin blue-green, and its formation is the first instance of an intramolecular change in the anthracene group. "*Alizarin indigo-blue*," which is produced by the further action of sulphuric acid on Alizarin blue-green is a mixture of two trihydroxy-alizarin blues, one identical with and the other isomeric with the body obtained by the authors direct from alizarin blue. The product of the action of sulphuric acid at 200° on Alizarin green is not identical with the above as stated in the patent, but consists of the monosulphonic acid of a dihydroxy-alizarin blue. The constitutional formulae of these products is under investigation.

Manufacture of Diaethyldibenzylidamido-diphenylmethane Disulpho Acid and Violet Dye Stuffs therefrom. J. R. Geigy, Basle, Switzerland. Eng. Pat. 21,284, December 31, 1890. 4d.

THE process depends upon the discovery that formaldehyde can be condensed with ethylbenzyl-aniline sulphonic acid forming diethyldibenzylidamido-diphenylmethane disulphonic acid, which, by suitable treatment, yields a violet dye for wool. The various stages for the production of the colouring matter, which can all take place in the same aqueous solution, are as follows:—(1.) Condensation of ethylbenzylaniline sulphonic acid with formaldehyde. (2.) Oxidation of the diethyldibenzylidamido-diphenylmethane disulphonic acid thus formed to diethyldibenzylidamido-benzhydrol disulphonic acid. (3.) Condensation of this last product with dimethyl- or diethyl-aniline, forming dimethyldiethyldibenzyl- or tetraethyldibenzyl-paraleuk-aniline disulphonic acid. (4.) Oxidation of these leuco-disulphonic acids into the sulphonic acids of the colouring matter.—T. A. L.

Production of Azo Colouring Matters. O. Imray, London. From the "Farbwerke vormals Meister, Lucius, und Brüning," Hoechst-on-the-Maine, Germany. Eng. Pat. 20,889, December 22, 1890. 6d.

BLUE to bluish-violet colouring matters are obtained by combining the diazo compounds of diphenylamine, phenyltolylamine and ditolylamine, their isomers, and homologues with various hydroxynaphthalene sulphonic acids, all of which are the subjects of German patents.—T. A. L.

VII.—ACIDS, ALKALIS, AND SALTS.

Oxidation of Cobalt Salts by Electrolysis. H. Marshall. *Jour. Chem. Soc.* 1891, 760—771.

In the course of some experiments on the electrolytic separation of copper and cobalt by Claisen's method, it was observed that a solution containing at the outset the sulphates of these metals together with potassium sulphate and sulphuric acid assumed a greyish green colouration though the copper had been completely precipitated. On addition of a reducing agent to such a solution the colour changed from green to pink, and in the particular case of hydrogen sulphide, sulphur was precipitated. Analytical results also showed that oxidation had taken place, and further experiments showed that the solution was decomposed by easily oxidisable substances; for example, hydrogen peroxide caused a rapid evolution of oxygen and hydrochloric acid of chlorine. It appeared that in the course of electrolysis the cobaltous sulphate was oxidised to the cobaltic salt, possibly in accordance with the equation $\text{CoSO}_4 + 2\text{CoSO}_4 \rightarrow \text{Co} + \text{Co}(\text{SO}_4)_2$. To confirm this supposition a solution of cobaltous sulphate was subjected to electrolysis, and solution of ammonia was then added to form ammonium sulphate with the free acid, and the current continued as before. Small dark-blue crystals were produced which were found to be the ammonium alum of cobalt. Again, by the electrolysis of cobaltous sulphate by itself a cobaltic salt, $\text{Co}(\text{SO}_4)_2 \cdot 18\text{H}_2\text{O}$, was obtained, which would be analogous to neutral aluminium sulphate, $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$, known as bar salt.

Simultaneously with the author's experiments, Kehrman, (Ber 19, 3101) had prepared a double cobaltic-potassium oxalate, which forms a green solution, and by the electrolysis of a saturated solution of cobaltous and ammonium oxalates the author obtained an ammoniumcobaltic oxalate, $\text{Co}_2(\text{NH}_4)_6 (\text{C}_2\text{O}_4)_6 \cdot 6\text{H}_2\text{O}$ corresponding in composition to the potassium salt. It forms nearly black prisms dissolving readily in water, to give a dark-green solution; in thin films the salt exhibits dichroism. Its solution is slowly decomposed, when boiled, depositing the cobaltous salt; it is unstable by ordinary reducing agents in the cold; when heated with strong hydrochloric acid the solution changed from a green to a blue colour with formation of anhydrous cobaltous chloride.—V. H. V.

The Persulphates. No. 5. H. Marshall. *J. Chem. Soc.* November 1891, 783—783.

The 6th part of a series of papers, concluded for the present with promise of future work and communications. Though the persulphates would seem not to be isomorphous with the perchlorates, they offer many close resemblances to them, as e.g. in the matter of solubility. Barium persulphate is a soluble and unstable salt. Sodium, lithium, and magnesium persulphates could not be prepared directly by electrolysis. The zinc salt was obtained by double decomposition between zinc sulphate and barium persulphate, but it rapidly decomposed. Efforts to prepare the copper salt were as unsatisfactory.

The Persulphates. H. Marshall. *J. Chem. Soc.* 59, 771—786.

The general method adopted by the author for preparing persulphates consisted in the electrolysis of the acid sulphates in an apparatus in which the cathode was represented by a stout platinum wire contained in a porous cell placed in a platinum basin, which was made the anode and was kept cool by immersion in a vessel through which water was allowed to circulate.

Potassium Persulphate, KSO₈.—The salt prepared by the electrolysis of potassium hydrogen sulphate forms colourless crystals, usually tabular, but sometimes assuming the shape of long prisms; their exact geometrical character has not yet been determined. 100 parts of water at 0° C. dissolve 1.77 parts of the salt; the solution decomposes slowly with formation of potassium hydrogen sulphate and liberation of oxygen, but even in contact with a zinc-copper couple the completion of decomposition is slow. Potassium persulphate is more insoluble than the corresponding salt of any other metal, and the precipitates it yields with metallic solutions are therefore not persulphates, but result from the formation of decomposition products. It is a powerful oxidant, precipitating lead, silver, and copper, as peroxides, and behaving similarly with salts of manganese, cobalt, and nickel in the presence of an alkali. It liberates iodine from potassium iodide, bleaches organic colouring matters such as litmus and turmeric, and oxidises potassium ferrocyanide to ferriocyanide, and causes paper and cloth to become rotten after having been dipped in its aqueous solution. Aqueous alcohol is oxidised by it to aldehyde, but absolute alcohol is not attacked, the persulphate being insoluble in that liquid. Pure potassium persulphate is odourless, but after having been kept for some time a peculiar smell is noticeable on opening the bottle containing it; in the case of a not very pure product ozone is slowly evolved; the salt has a cooling saline taste, but leaves a peculiar after-taste possibly due to persulphuric acid.

Ammonium Persulphate, NH₄SO₈. is prepared in the same way as the potassium salt, and forms colourless prisms or lozenge-shaped tables. 100 parts of water at 0° C. dissolve 58.2 parts of ammonium persulphate; its great solubility makes it difficult to purify, and causes it to give, as a rule, more marked reactions than the potassium salt; it is moreover less easy to keep.

Barium Persulphate, Ba(SO₄)₂ · 4H₂O, is best formed by treating a saturated solution of ammonium persulphate with barium hydrate. During the evaporation of its solution a certain amount of decomposition takes place, barium sulphate separating out and persulphuric acid being liberated. It forms prisms sometimes deeply striated or arranged in stellate groups. The crystals decompose on keeping, and are best preserved in a damp atmosphere. 100 parts of water at 0° C. dissolve 52.2 parts of the crystallised salt, corresponding to 39.1 parts of the anhydrous body; the solubility is considerably greater at higher temperatures, and the salt readily forms supersaturated solutions. The crystallised salt is soluble in absolute alcohol without decomposition, a portion being, however, precipitated on standing in the dehydrated state. It is decomposed, however, by dilute alcohol, aldehyde being formed and oxygen liberated. The salt, after dehydration by means of alcohol, has the formula $\text{Ba}(\text{SO}_4)_2 \cdot \text{H}_2\text{O}$, the last molecule of water being eliminated only when the salt is decomposed; in this respect it resembles the perchlorate.

The persulphates of lead, zinc, and copper have been prepared, though with difficulty, and have not yet been obtained pure on account of their tendency to decompose; attempts to prepare the persulphates of sodium, lithium, and magnesium directly by electrolysis proved unsuccessful.

From these results the author concludes that the peroxide of sulphur, S_2O_2 , forms a true acid, persulphuric acid H_2SO_5 , in the manner indicated by Berthelot, contrary to the assertions of Mendeleef and Traube.—B. B.

On the Changes of Colour of Nitric Acid.

L. Marehlewski. Ber. 1891, 24, 3271—3276.

When water is gradually added to concentrated red fuming nitric acid, the acid, as is known, first assumes a green colour; next, as the further additions of water is continued, a blue colour supervenes, and finally, when further diluted, the liquid becomes colourless. If the experiment be reversed, i.e., if concentrated fuming acid be added little by little to water, first a blue colour appears, then a green, and finally a red-brown colour.

It has been usual to explain these colour changes on the assumption that a portion of the nitrogen peroxide in the red acid becomes decomposed by the addition of a little water, forming nitrous acid, the blue colour of which blending with the brown colour of the still undecomposed nitrogen peroxide in the fuming nitric acid produces a green colour in the latter. On a further addition of water more of the nitrogen peroxide is decomposed, and the blue tint becomes stronger.

Similar changes of colour take place when nitric oxide is led into nitric acid. Nitric acid of sp. gr. 1.25, when treated with nitric oxide, gives a blue colour, acid of sp. gr. 1.35 gives a green colour, whilst concentrated acid (sp. gr. 1.48—1.50) gives a red-brown colour. These degrees of concentration correspond to those which give the same colours respectively when concentrated acid is diluted with water. The action of nitric oxide on a dilute nitric acid produces nitrous acid, $2NO + HNO_3 + H_2O = 3HNO_2$, whilst nitric oxide and a concentrated acid yield nitrogen peroxide and water, $2NO + 4HNO_3 = 3N_2O_4 + 2H_2O$. The explanation given above to account for the colours would hold good also, therefore, in the case of the colours produced by leading nitric oxide into nitric acids of various strengths.

The author has endeavoured to obtain a verification of this explanation by driving out the gases from the various coloured acids by a stream of carbonic acid gas, and absorbing the evolved gases in sulphuric acid. Bearing in mind that nitrous acid and concentrated sulphuric acid yield pure nitrosylsulphate, whilst nitrogen peroxide and sulphuric acid yield an equal number of molecules of nitrosylsulphate and of nitric acid, we have a basis for estimating the relative quantities of these two gases in the coloured nitric acid—

If, now, the nitrosylsulphate be estimated in the first place by determining the nitrogen in a Lunge gas volumeter, and next by titration with potassium permanganate, the relative proportions of nitrogen trioxide and nitrogen peroxide that have been expelled from the nitric acid can be calculated.

The following table shows the results obtained. The first column gives the kind of gas by which the colour of the acid was produced; column two gives the specific gravity of the nitric acid used; the third column states the colour produced, and the last column gives the ratio of the nitrous acid calculated by the method of titration to the quantity as determined by the gas-volumetric way. When the ratio equals 1 the sulphuric acid contains only nitrosylsulphate, and the corresponding coloured nitric acid contained only nitrous acid; when the ratio is less than 1, nitric acid was also present in the sulphuric acid, and the corresponding coloured nitric acid contained a mixture of nitrous acid and nitrogen peroxide; when the ratio equals 0.5, the corre-

sponding coloured nitric acid contained only nitrogen peroxide:—

1. NO.....	1.210	Blue	1.002
2. NO.....	1.275	Blue-green	1.008
3. NO.....	1.375	Green	0.808
4. NO.....	1.400	Dark green	0.721
5. NO.....	Highly conc.	Red-brown	0.551
6. N_2O_3	1.210	Blue	1.010
7. N_2O_3	1.275	Blue-green	1.004
8. N_2O_4	1.275	Green	1.001

These results do not bear out the accepted explanation of the colours of the nitric acid. Although it is shown that the blue solutions really seem to contain only nitrous acid, yet it is also shown that the blue-green and green solutions, which according to the theory ought to contain a mixture of nitrous acid and nitrogen peroxide, contain in reality only nitrous acid, or at any rate mixed with only a very small quantity of nitrogen peroxide. The last experiment gives a result in direct opposition to the accepted theory.

The author next endeavoured to find out whether nitric oxide was also present in the gases evolved from the blue-green and green coloured acids, and he found that this was the case. He estimated this oxide by absorbing it in a solution of semi-normal potassium permanganate, after removing first of all the nitrous acid and nitrogen peroxide by absorption with sulphuric acid. The amount of potassium permanganate consumed showed the quantity of nitric oxide present. In two cases given in the paper, considerable amounts of nitric oxide were found to be present. Whether it plays a part in the production of the colours or not, or is a product of decomposition of some unknown nitrogen compound, or whether its presence is due to the manner of preparing the coloured acids, has not been elucidated. It is possible that here, however, may be found a rational chemical explanation of the fact noticed by Gernez (Compt. Rend. 74, 465) that red fuming nitric acid does not give the characteristic absorption spectrum of nitrogen peroxide until after a drop of carbon disulphide has been added to it.

—H. S. P.

Heat of Evaporation of Liquid Ammonia. H. von Strombeck. Journ. Franklin Inst. 1891, 131, 470—476.

From a series of 12 carefully made experiments, the author deduces an average value of 533.7 English thermal units for the heat of evaporation of liquid ammonia. The author's previous experiments (Journ. Franklin Inst. 1890, 130, 481; this Journal, 1891, 638) gave a mean of 526.32 thermal units.—S. B. A. A.

Improvements in the Manufacture of Chlorine. J. Simpson, Liverpool. Eng. Pat. 19,776, December 4, 1890. 4d.

CHLORIDE of sodium is decomposed by means of phosphoric acid at a red heat, as described in the inventor's patent 18,835 of 1890 (this Journal, 1891, 768), sodium phosphate being formed and hydrochloric acid gas evolved. The hydrochloric acid thus obtained "is practically free from nitrogen and will work much better in the Deacon decomposer for the production of chlorine than the gas from the ordinary salt-cake process." As an alternative method for obtaining chlorine, hydrochloric acid gas is generated as above described, and is conducted together with a sufficient quantity of oxygen to combine with the hydrogen of the hydrochloric acid through a heated chamber filled with marbles (preferably glazed). Chlorine is thus liberated as expressed by the equation $2\text{HCl} + \text{O} = \text{H}_2\text{O} + 2\text{Cl}$. Oxygen produced by any known means may be used, but that made by the method known as Brin's process is preferred.—H. S. P.

Improvements in and connected with the Treatment of Crude Bicarbonate of Soda to obtain Caustic Soda, Carbonic Acid, and other Products. A. Campbell, Glasgow; W. Boyd, Thornton; A. J. Kirkpatrick, Glasgow. Eng. Pat. 21,071, December 27, 1890. 6d.

SODIUM bicarbonate from the ammonia-soda process is charged in a series of wrought or cast iron vessels, and there treated with a current of steam, which enters the series at the bottom of the particular vessel which is next to be emptied; after passing through all the vessels, it escapes from the newly charged one, to which sufficient water has been added, to enable the final formation of a solution of say 10 Tw. The escaping gases consist of carbonic acid and traces of ammonia; the latter is retained by washing with brine, which returns to the ammonia-soda process, and the remaining nearly pure carbonic acid is available for other purposes. Hot lime-kiln gases may be used instead of steam, whereby the escaping gases will be considerably richer in carbonic acid. When the conversion into monocarbonate is sufficiently completed, the charge is run off into an agitator and emulsified with milk of lime. Caustic soda and calcium carbonate are formed; the sludge may be washed and elutriated and used for distilling off ammonia as carbonate from the ammonium chloride of the ammonia-soda process; or the lime sludge may be filtered— "in which presses it is made as free as possible from soda;" the filter cakes are then moulded into bricks which may be burnt in a kiln into caustic lime and carbonic acid; or the sludge may be used for making cement.—H. A.

Improvements in the Treatment by the Claus Process of Gases containing Sulphuretted Hydrogen and Recovery of Valuable Products therefrom. C. W. Heaton, London. Eng. Pat. 21,217, December 30, 1890. 8d.

THE invention relates to the treatment of the gases passing from the Claus kiln. After the sulphur has been condensed in the usual way the cooled gases containing small but varying quantities of free sulphur, sulphuretted hydrogen, and sulphurous acid, are mixed with sufficient or more than sufficient air to oxidise all the sulphur and sulphuretted hydrogen, and are then led through heated tubes or chambers packed with oxide of iron or an oxide of manganese, the apparatus being designated by the inventor as a "supplementary Claus kiln." The whole of the sulphur, free and combined, in the gases is thus converted into sulphurous acid, after which the gases are caused to ascend a tower packed with limestone, chalk, or flint, where they meet a descending stream of water, or a solution of carbonate of soda, or of caustic soda, or other alkaline liquid which dissolves the sulphurous acid. If the tower be packed with limestone and the wash-liquid be water, the solution obtained may be run away, but if an alkaline liquor be used, alkaline sulphates are recovered, which will be of commercial value.—H. S. P.

Process for obtaining Pure Nitric Acid Direct in Nitric Acid Reaction Apparatus. O. Imray, London. From the "Chemische Fabrik Griesheim," Frankfurt, Germany. Eng. Pat. 891, January 17, 1891. 4d.

ATTACHED to the producing apparatus is a collecting vessel into which flows the acid condensed by a reflux cooler. The acid in the collecting vessel is maintained at a temperature of about 80° C., and the reflux cooler is worked so that the lower oxides of nitrogen, and the halogen compounds, as free from nitric acid as possible, escape. "The production of a pure acid, even at the temperature of 80° C., is considerably facilitated by conducting air or other gases into the acid in the collecting vessel."—H. S. P.

Improvements in the Manufacture of Sodium Biborate or Borax, Sodium Crystal Carbonate or Soda, and other Compounds containing Sodium or Boron, or both. J. Asconth, Birmingham. Eng. Pat. 3230, February 23, 1891. 6d.

THE object of this invention is the manufacture of compounds containing sodium or boron, or both, in small crystalline or granular masses, or in a pulverulent state. For the production of granular borax 4 mols. of boric acid and 1 mol. of crystallised sodium carbonate (or also dry sodium carbonate, in which case sufficient water has to be added to replace the water of crystallisation) are dissolved in water, and the mass, "if needful," evaporated "to such a consistency that on cooling it will readily form into small crystals, crystalline, or granular masses, or become pulverulent sodium biborate or borax." The solution may be cooled in shallow pans, and any means may be applied to "bring about the state most favourable for small crystals," &c. For the production of granular sodium crystal carbonate the inventor takes 100 parts of dry sodium carbonate, 250 parts of water, or a sodium carbonate solution containing these proportions, and proceeds "to bring about combinations and crystallisation, as already described for sodium biborate." Or the process of crystallising may be continued in the ordinary way until large crystals begin to form, and then the solution is evaporated "to such density that small crystals will readily form." The patentee wishes it to be distinctly understood that he does not bind himself "to the exact details here given," but simply claims to "avoid the production of mother-liquors and the consequent waste and loss of time inseparable from the manufacture of large crystals."—H. A.

Improvements in the Production of Alkaline Carbonates and Chlorine, and their Derivatives. F. M. Lyte, London. Eng. Pat. 5352, March 25, 1891. 8d.

THE invention is based on a reaction described by Lunge, wherein two equivalents of sodium nitrate and 2½ equivalents of calcium carbonate are heated together to form sodium carbonate, caustic lime, and oxides of nitrogen; by lixiviating the resulting mass with a large quantity of water caustic soda is obtained. The escaping gases (oxides of nitrogen) are converted into nitric acid by the simultaneous action of air and water in suitable chambers. It is proposed to utilise this nitric acid for dissolving litharge, and to decompose the resulting lead nitrate with salt, forming insoluble lead chloride, and a solution of sodium nitrate. The latter is evaporated and returns to the process along with the calcium carbonate left on lixiviation of the above melt. The lead chloride is fused and subjected to electrolysis, whereby it is split up in its constituents, chlorine separating at the anode and lead at the cathode, from whence it may be continually run off. The recovered lead is oxidised into litharge with some of the recovered nitric acid, and entering into solution returns to the process.

The electrolysis of the fused lead chloride may be performed in a graphite, earthenware, or enamelled iron vessel, heated to a suitable temperature. The graphite anode is fastened to the inside of a bell which is immersed in the fused mass; the cathode is made of tinned iron and passes in at the bottom of the electrolysing vessel. An electromotive force of 2–5 volts is sufficient for the purposes of the electrolysis.—H. A.

Improvements in Lead Chambers used in the Manufacture of Sulphuric Acid. K. Walter, Milan, Italy, and E. Boenig, Bad Nauheim, Germany. Eng. Pat. 14,944, September 4, 1891. 4d.

To insure the more perfect and continuous circulation of the gases within sulphuric acid chambers, double walls of acid-proof material are built right across the chambers. The space between the double walls is filled with suitable acid-proof materials such as brick or coke. Openings are provided in these walls over their whole width, the openings in the front wall being at the top, and those in the back wall at the bottom of the wall or *vice versa*. The gases enter the openings in the front wall, and traversing vertically the interstices of the packing pass onward through the openings in the back wall, while at the same time some portion of the gases may penetrate horizontally through cracks and joints in the walls.—H. S. P.

Improvements relating to the Manufacture of Ammonia and Gas. W. R. Lake, London. From A. Hennin, Springfield, U.S.A. Eng. Pat. 15,249, September 8, 1891. 8d.
See under H., page 996.

Process for Purifying Brine. C. G. Collins, Wood-burgh, U.S.A. Eng. Pat. 15,251, September 8, 1891. 8d.

THE most common impurities of brine consist of the bicarbonates of iron, calcium and magnesium, calcium sulphate, calcium chloride, and magnesium chloride. The inventor finds that an electric current having an electro-motive force not exceeding $2\frac{1}{2}$ volts is sufficient to decompose these impurities, rendering them insoluble, whilst the sodium chloride is not acted upon at all. As an instance the electrolysis of calcium bicarbonate proceeds in such a manner that carbonic acid is given off on the anode, and calcium hydrate on the cathode, which acting on another molecule of bicarbonate, converts it into insoluble calcium monocarbonate which settles out. The sediment is collected on the bottom of the electrolytic vessel, from whence it may be discharged at intervals, whilst the purified brine is tapped off at a higher level. An alternate method of working consists in forcing the liquor and precipitate, by hydrostatic pressure, through a filter bed, in which are embedded the electrodes of another battery, by which means the redissolving of the precipitated impurities is prevented. A sheet of drawings accompanies the specification.—H. A.

Improvements in and Relating to the Art or Process of Manufacturing Phosphoric Acid from Phosphatic Material. C. Glaser, Baltimore, U.S.A. Eng. Pat. 15,644, September 15, 1891. 4d.

IN the ordinary process of manufacturing phosphoric acid from phosphatic material the phosphatic material is treated with dilute sulphuric acid, yielding a weak solution of phosphoric acid which is then concentrated by evaporation. The improvement on this process consists in using the weak solution of phosphoric acid obtained by the action of dilute sulphuric acid on phosphatic material, to dilute the sulphuric acid for the treatment of a second batch of phosphatic material, instead of using water as the diluent. The treatment of the second batch yields a stronger solution of phosphoric acid than that obtained from the first batch, and this solution is again used to dilute the sulphuric acid for the treatment of a third batch, again yielding a still stronger acid. This process may be advantageously continued until a solution of phosphoric acid of about 30° B. is obtained, beyond which point filtration from the insoluble residue becomes difficult, and it becomes advisable to continue the further concentration of the phosphoric acid by evaporation in the usual way.—H. S. P.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

PATENTS.

A New or Improved Portable or Fired Continuous Firing Kiln for Burning or Staining Glass, China, Tiles, Enamels, and Ceramic Ware, also applicable to other Purposes. J. W. Payne, London. Eng. Pat. 16,131, October 11, 1890. 6d.

THE kiln consists of a number of chambers placed over each other in small kilns, and side by side in large ones, one of which is directly heated, whilst the others receive the waste heat in succession. These chambers are provided with doors and ledges for the metal plates, which carry the articles to be fired, to rest upon, and are supported on a heat-spreading and accumulating arrangement, which facilitates the rapid heating by the furnace gases. The articles to be burnt are introduced into the coldest chamber and gradually transferred to the hotter ones, and the process is thus conducted without the products of combustion coming into contact with the objects fired. In the specification illustrations are given of the details and also of an arrangement for facilitating the removal of the chambers when worn out and the substitution of new ones.—S. B. A. A.

Improvements in the Manufacture of Glass Retorts as used in Chemical Works for the Concentration of Acids and other Analogous Purposes. T. G. Webb, Manchester. Eng. Pat. 17,407, October 31, 1890. 6d.

THE object of this invention is to make a chemical manufacturer's retort which shall be of the same thickness of glass throughout, instead of being thicker towards the shoulder and mouth, as heretofore, and which is in consequence more durable than a retort of the old form. The operation is effected by taking from the furnace the quantity of "metal" needed to make a finished retort, and at once shaping the neck "by hanging the metal downwards, which draws out the neck to the required length, and to a form tapering outwards, instead of by rolling and shaping the neck on the edge of a plate by a series of heatings, and to a shape tapering inwards as heretofore, whilst the remaining portion of the retort is reheated, rolled and shaped, and simultaneously blown to the desired form and size."—H. S. P.

Improvements in and relating to Enamel for Metals, Glass Ware, Earthenware, and other Materials. G. Gehring, Landsht, Germany. Eng. Pat. 8090, May 11, 1891. 4d.

THESE improvements relate to various compositions used for the production of enamels. One particularly fine enamel is said to be produced by using graphite, cold-pressed Hungarian linseed oil, and oxide or borate of lead. The inventor claims the "process for enamelling metals, earthenware, and glassware, consisting in mixing a powder of graphite, coke, slag, alum, and kaolin, or one or more of these materials, with a flux, rubbing up the mixture with a compound obtained by boiling linseed oil with an oxide or a borate of lead, and laying on, drying, and burning the same;" or powdered kaolin may be mixed with a flux and the mixture "rubbed up" with water afterwards laying on, drying, and burning.—O. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

PATENTS.

Improvements in the Manufacture of Decorative Material for Walls and other Decorative Purposes, and in the Machinery or Apparatus Employed in the said Manufacture, the said Improvements being in part applicable to the Manufacture of Felt Papers and Millboard. T. J. Palmer, Carshalton. Eng. Pat. 4227, September 3, 1883. (Second Edition.) *8d.*

See under XIX. page 1022.

An Improved Artificial Asphalt. H. P. and E. G. Williams, London. Eng. Pat. 13,595, August 29, 1890. *4d.*

As asphalt which is said to resist the action of acids is produced by mixing silver sand or other suitable sand with pitch, from which all creosote or "creosote salts" have been removed.

The product is stated to be especially suited for the lining and flooring of rooms containing electric batteries, for the construction of tanks to contain acids, &c.—O. H.

Improvements in or Relating to the Manufacture of Cement and the Means employed therefor. T. Arnold, West Hartlepool. Eng. Pat. 18,603, November 18, 1890. *8d.*

THE improvements claimed by the patentee comprise the use of a kiln for burning cement by means of coal, the products from which are passed into a chamber termed the drying chamber, thence under floors in the ordinary way, and finally to the chimney. The slurry from the drying floors is moulded into bricks in the drying chamber, and is transferred thence to the calcining kiln, which may be situated at a level below the drying chamber and the floors, or should the configuration of the ground render this arrangement costly, may be separated from the drying chamber by means of an arch. It is claimed that the imperfectly burned products of combustion from the kiln deposit carbonaceous matter in the interstices of the bricks in the drying chamber, and subsequent combustion of which completes the drying process. The patent also includes a claim for the use of a large door at the entrance of the calcining kiln, capable of removal when the contents of the latter have reached a clinkering temperature, thus causing their disintegration and facilitating the grinding. It is also stated that the temperature in the calcining kiln can be gauged by the state of the slurry on the drying floor, and thus the process of burning regulated. The improvements are said to be applicable to many forms of kilns and drying apparatus.—B. B.

X.—METALLURGY.

On the Use of Liquid Fuel in Copper Smelting. C. Schnabel. Zeits. des Ver. Deutsch. Ing. 1891, 1027, and Abstr. Proc. Inst. Civil Eng. 1891, 105, 55.

AT Messrs. Siemens' copper-smelting works at Keldaberg, in the Transcaucasus, the residues from naphtha distillation have been applied experimentally both in the calcination and fusion of pyritic ores, the furnaces for both operations being combined into one structure, having a chimney stack in common.

The smelting furnace has a circular bed 6 metres in diameter, covered by a domed roof, having a maximum height of $2\frac{1}{2}$ metres in the centre. The heating is done by

two of Lenz's atomising burners placed about 3 metres apart on the same side of the furnace, with the up-take flue between them. The jets are not quite square to the admission port, so that two eddying bores of flame are produced under the roof, which unite and pass out by the flue over the bed of the calcining furnace. The latter is 16 metres long, with a bed 2·8 metres wide, and 0·95 metre height of roof, which is laid with an upward slope of nearly 1 in 7.

The ore, containing 7 per cent. of copper, is in the ordinary way, first roasted and then run down to coarse metal containing 25 per cent. of copper; but when the roasting is omitted the regulus contains only 18 or 20 per cent. of copper.

With this furnace in 33 working days 938·6 tons of ore were smelted, yielding 368·2 tons of coarse metal, averaging 25 per cent. of copper, with a consumption of 185·6 tons of naphtha residues, or rather more than 10 ewt. (50·43 per cent.) of the weight of the product.

The Effects of Abnormally Low Temperatures on Constructional Iron. F. Steiner. Iron, 1891, 38, 269—270.

THE author communicates the results of some interesting experiments which he made with a view of determining the influence exercised on iron and steel by a very low temperature. The tests were conducted with three different materials, viz., welded iron, ingot iron, and English cast steel. Strips of each sort, measuring 20 centimetres in length, 3 to 5 centimetres in width, and 7 to 10 millimetres in thickness, were used, and a separate strip of each class was laid on one side for the purpose of comparison. In the first place the static qualities of the three metals were established as follows:—

Metals.	Breaking Strength.	Extension.	Sectional Contraction.
		Per Cent.	Per Cent.
Welded iron....	3,500	18	20
Ingot iron.....	3,600	30	60
Cast steel.....	6,000	4	9

Half of the test pieces were experimented upon in an undamaged condition; the other half were notched about one millimetre deep with a chisel on one side in the middle. It will be seen from the results that these notches substantially influenced the subsequent behaviour of the metals. The pieces of iron and steel were refrigerated in a so-called freezing bag composed of two velvet wrappers. The pieces were placed in a row in this bag. At its upper end a flask filled with liquid carbonic acid was brought in connection with the bag in an inverted position; on opening a valve the liquid carbonic acid flowed from the flask, entered the freezing bag, and either immediately evaporated, or escaped through the pores of the velvet. So much heat was thereby imprisoned that a portion of the carbonic acid in the freezing bag was transformed into a snow-like mass of solid carbonic acid, which attached itself to the iron and steel test pieces. This process was continued until the metallic strips were completely enveloped in solid carbonic acid. The double velvet wrappers constitute so bad a conductor of heat that the carbonic acid remains for hours in a solid condition. After a test piece had been left in the freezing bag for 30 minutes, it was taken out with a squeezer and trials were made of its solidity. To this end it was laid concavously over a mould of the following form. A piece

of round bar iron was laid diagonally across, to receive the very light blows of a small steam hammer, and to transfer them to the test piece. The most important results

were as follows:—(1) The three classes of iron, after being powerfully refrigerated, and then allowed to gradually regain their normal temperature, showed no appreciable alteration in the bending test. (2) Undamaged welded iron in the refrigerated state was bent to an angle of 180° without breaking; the notched piece could not be bent further; the broken surface, fibrous in the unrefrigerated condition, presented a granular appearance in the refrigerated state. (3) Soft, undamaged ingot iron, and also the steel, after undergoing a slight bending, on receiving the third weak blow of the hammer sprang asunder with a crackling noise as of glass. The notched or damaged test pieces of these two sorts burst in two in the same manner at the first light blow without submitting to the bending experiment. The broken surfaces of the refrigerated pieces showed a grain formation, the steel an almost coarse-grained structure. These trials clearly demonstrated the prejudicial effects of intense cold upon these building materials, and the following conclusions are to be drawn—namely, that ingot-iron bridges should be crossed but slowly when abnormally low temperatures prevail, and that every care should be taken in building to avoid external fractures of the ingot-iron constructional parts of a bridge.

The foregoing details originally derived from the "*Wochenschr. des österr. Ing. und Arch. Vereins*," are also reported in "*Stahl und Eisen*," in which, after the statement that the trials probably need further confirmation, the following further details are given:—The refrigerating tubes in the ice machines, and also the iron cylinders for the transport of liquid ammonia, compressed oxygen, liquid sulphurous acid, and liquid carbonic acid are now only made of the best fibrous welded iron. Many explosions of iron cylinders containing liquid carbonic acid are to be explained by the action of the low temperatures, and this danger can be avoided by the use of proper kinds of soft but sufficiently strong-welded iron. Although refrigeration experiments with the three different kinds of iron and steel referred to were tried at the low temperatures of -40° to -50° , yet under other and very unfavourable circumstances though at temperatures of less depression, even in the best iron considerable crystalline alterations and localised looseness of texture may be brought about, when the metal is at the same time subjected to sudden and powerful concussions. In the very cold winter of 1880 (in the Rhine valley in some places it was -26° C.) many experiences of this kind were encountered in rails and connexions. But iron is not the only metal so affected that a crystalline texture is the result of strong cooling. Tin behaves in the same way though in a still higher degree, as shown by Fritzsche in 1869 (*Ber.* 1869, 2, 112). In the very cold winter of 1867–68 some blocks of barred tin became entirely crystalline, or nearly so, suffering dilation or swelling up in the process, and becoming in parts converted into a sandy crystalline or granular powder. A similar crystalline conversion was noticed also in a tin tube. Erdmann, of Leipzig, observed the same thing in organ pipes made of tin.—O. H.

must have weighed about 41 oz. before it was put in the crucible, only weighed 14½ oz. when taken out, while another was reduced from 26½ oz. to 8½ oz. The quantities that fused and ran out were therefore 64½ and 66½ per cent. of the original masses respectively. Analysis showed that both these shells contained less than 0.1 per cent. of carbon, this fact accounting for their infusibility. The change in composition may have been due to the concentration of the carbon and other non-metals in the interior of the metal, or to their being burnt out by the surface action of the air. The author considers that the phenomenon in question points to the desirability of retaining the natural skin of castings and forgings whenever it is possible to avoid removing it by machinery.—B. B.

The Elimination of Sulphur from Pig Iron. J. Massenez. Proc. Iron and Steel Inst. "The Ironmonger," 1891, 57, 100–103.

In both acid and basic Bessemer processes the varying proportions of non-metals in the pig iron charged into the converter are a constant source of trouble, which can, however, be obviated by the use of W. R. Jones's mixing process, in which 70–120 tons of pig iron, sufficient for 7–12 charges, are placed into one common mixing vessel and taken for consumption into steel as required. In the treatment of phosphoric pig iron which is employed in the production of basic steel, it is, however, not sufficient merely to conduct the molten pig iron in large quantities to the converter in a mixed condition, but the problem here is to render the proportion of sulphur also independent of the blast-furnace process, to such an extent that the proportion of sulphur in the finished steel is so low that the quality of the steel is in no way influenced by it. This is especially important on the Continent, as, on account of the strike of the coal miners in 1889, an improved position of the strikers has resulted, the coal is less carefully mined and contains more sulphur, the amount in the coke having risen from 1 to 1.8 per cent.

It has been found that manganese will act upon the sulphur in pig iron, removing it as manganese sulphide. This operation is best conducted outside the blast furnace, as when effected therein the furnace has to be worked out, resulting in the production of iron "hotter" than is desirable for conversion. Accordingly, at Hoerde, where the process is at work, a vessel of the form of a converter, lined with refractory bricks, is used for the reception of the pig from the blast furnace, and to this ferromanganese is added. The quantity of manganese theoretically required is merely that needed to convert the sulphur into manganese sulphide, and in practice it has been found that 0.2 per cent. suffices, so that as 1.5 is the quantity that should be in the pig as it passes to the converter, the addition of 1.7 per cent. is necessary for the desulphurisation. The operation is completed in 15–20 minutes, even with pig high in sulphur. The bath of metal usually retains sufficient heat for the purpose of desulphurisation, thus rendering external sources of heat unnecessary. The following table shows some of the results obtained:—

An Undescribed Phenomenon in the Fusion of Mild Steel. F. J. R. Canula. Proc. Iron and Steel Inst. "The Ironmonger," 1891, 57, 98–99.

In 1773, H. Horne found that on heating ingots of cast iron about 3 in. thick in contact with calcined bones and powdered charcoal, their outer portion was so far changed in nature that they were capable of withstanding a welding heat without suffering fusion, whereas the core, when submitted to this temperature, melted and ran out. The author has observed a similar phenomenon with Bessemer scrap. A crucible charged with this steel (of varying carbon contents) having given way in the furnace, was withdrawn from the furnace under the supposition that it was empty, but was found to contain a number of shells having the shape of the pieces of steel originally charged; from which it was apparent that the inner portion of the pieces had undergone fusion, while the outside envelope had remained solid, presumably owing to a difference in their fusing points. One piece which, from the size of the shell left,

From Blast Furnace.	Percentage of Sulphur in the Charges poured into the Vessel (10–11 Tons of Pig Iron).	Percentage in Basic Charge (10–11 Tons) taken from the Vessel.	In Finished Steel.
	Per Cent. Sulphur.	Per Cent. Sulphur.	Per Cent. Sulphur.
II.	0.276	0.056	0.039
IV.	0.137	0.044	0.027
II.	1.022	0.043	0.034
II.	1.020	0.043	0.057
I.	1.530	0.043	0.041
IV.	0.680	0.054	0.032
IV.	0.352	0.034	0.018

Some of the samples were purposely made rich in sulphur to test the process. In a series of tappings, the details of which are given in the paper, from a total weight of 138,500 kilos, of pig iron containing 179,576 kilos, of sulphur, 80,923 kilos, of sulphur were eliminated, i.e. 45 per cent. of the total sulphur. Most of the sulphur appears in the slag, but little being volatilised as sulphurous acid. The following is an analysis of an average sample of slag:—

Manganese sulphide.....	28.01
Manganese oxide.....	20.23
Ferrous oxide.....	27.45
Alumina.....	5.00
Silica.....	18.90
Lime.....	3.53
Magnesium.....	0.13
Total.....	103.25

The Bismuth of Commerce and Purified Bismuth, together with some Remarks on the Atomic Weight of Bismuth. R. Schneider. J. Prakt. Chem. 1891, **44**, 23—48.

Reply to R. Schneider's Paper on the Bismuth of Commerce, &c. A. Classen. J. Prakt. Chem. 1891, **44**, 411—414.

See under XXIII., pages 1010—1041.

A New Use for Aluminium. Eng. and Mining J., November 21, 1891, 585.

A new use has been found for aluminium in the manufacture of cups, canteens, cartouche boxes, &c., for military equipments, a large order for metal for this purpose having recently been given in the United States by the German Government. It is the constant study of military experts to reduce the weight which the common soldier is obliged to carry, and the new departure of the Germans has this object.

Antimony in Nevada. Eng. and Mining J., November 21, 1891, 585.

Rich veins of antimony ore have been known to exist in Utah and Nevada for some time, but antimony mining has at last become a regular and profitable industry there. Early in the present year an English company was organised to acquire and work an antimony mine near Austin, Nevada. A good body of ore of excellent grade has been exposed in the mine, and regular shipments were commenced soon after the new company took possession of the property, the ore being sent to England for reduction. Last month the company declared its first dividend. The mine is said to be improving, and is now making an output of about 100 tons of ore per month.

PATENTS.

Improvements in or Connected with Reverberatory Furnaces for Puddling or Smelting Iron, and for other Purposes. J. von Langst and L. Cooper, Leeds. Eng. Pat. 17,380, October 30, 1890. 8d.

This is a reversible furnace of the Potoka type and consists of two hearths, which can be rotated on a vertical axis so as to change their position with relation to the flues. The chief features of this invention consist in having the hydraulic apparatus for tilting the hearth placed above instead of below the furnace, in having beneath the hearth-plates a rectangular chamber of sheet iron through which the air passes on its way to the furnace, the chamber being divided by partitions so that the air takes a zigzag course, and in having the line of junction of the furnace shaped so that the surfaces in contact form parts of two parallel and co-axial cones joined by a narrow annular strip.

—H. K. T.

Process for the Manufacture of Metallic Nickel, together with Alloys of Nickel and Iron, Utilisable either direct or for the Manufacture of Nickel Steel or Nickel and Carburetted Iron Castings. J. Garnier, Paris, France. Eng. Pat. 17,623, November 3, 1890. 6d. (Compare Eng. Pat. 1191 of 1876.)

This process applies chiefly to the ferruginous nickel oxide ores discovered by the patentee in New Caledonia. When these ores are fused in the blast furnace the product contains nearly the whole of the sulphur, arsenic, and phosphorus of the coke and of the fluxes of the bed of fusion, owing to the affinity of nickel for these elements. In order to remove these impurities the crude nickel is smelted in a water-jacketed furnace having a basic lining of magnesia, calcined dolomite, or chrome iron ore. A hot-blast is injected through tuyères arranged in superposed planes, and in order to thoroughly remove arsenic and silicon, the lowest series of tuyères are immersed in the fluid metal, the apparatus being so arranged that the slag and metal run off at the same time into a fore-hearth. The crude nickel containing nickel, iron, and sometimes copper, is charged into the furnace with coke and lime, magnesia or baryta, together with fluor spar or sea-salt, so that the ratio of the bases to the silica and fluor spar, or sea-salt is 3:1. The regulus obtained in this way is quite free from non-metallic elements, and is suitable (with or without the addition of iron) for the production of castings which are very slightly oxidisable. The cost of using pure nickel is thus avoided. When nickel steel is required, the regulus is simply added to the crucible, Siemens furnace, or Bessemer converter, as the case may be.

When comparatively pure nickel is required the above regulus is submitted to an energetic oxidising action in a refining furnace or Bessemer converter, whereby the iron and last traces of carbon and silicon are oxidised. Admixed oxides are then removed by the addition of a reducing agent such as manganese, magnesium, aluminium, or zinc. The nickel so obtained is very soft.—H. K. T.

Improvements in Furnaces for Smelting Copper and other Ores. B. Richards, Middlebank, Swansea. Eng. Pat. 17,625, November 3, 1890. 6d.

This is a furnace for the smelting of copper ores in one operation, instead of using the usual reverberatory and metal furnaces and metal roaster. It consists of an oblong furnace with tuyères at the top and sides, and resembles in shape a number of square cupola furnaces placed side by side with their partition walls removed. The bottom of the furnace slopes towards one end, and there the rich molten metal collects and is drawn off, whilst the slag, containing some metal, flows over a bridge into a smaller furnace. It is here mixed with more fuel and inferior slag or ore when the rest of the metal separates and is tapped. The slags are sufficiently free from metal to render further purification unnecessary.—H. K. T.

Improvements in the Extraction of Metals from Ore. W. Paterson and R. Starke, Glasgow. Eng. Pat. 18,934, November 22, 1890. 8d.

This is a combination of leaching vessels for the systematic extraction of ores by solutions of chlorine, bromine, or iodine. The vessels are arranged in a circle, and their upper ends are connected with a pipe or pipes, taps being placed between each vessel; the lower ends are similarly connected with a circular pipe. The upper end of each vessel can also be put in communication either with a force pump or a vertical tube to convey the liquor to a reservoir. At starting, the vessels are charged with ore and the taps are arranged so that the liquor from the force pump enters the top of one vessel, passes down it, and is led to the bottom of the next, up which it flows, and is then led to the top of the third vessel, and so on to the last vessel which is put in communication with the vertical tube. When the ore in the first vessel is exhausted, the vessel is cut out of the series and is re-charged through manholes

with which it is provided, and is then re-connected with the stream of fluid, but this time it is made the last of the series, and in this way each vessel is in rotation made the first to receive the extracting fluid.—H. K. T.

Improvements in the Manufacture of Steel. H. C. S. Dyer, Westhope. Eng. Pat. 20,393, December 13, 1890. 4d.

WHEN using the acid or basic process in an open-hearth furnace the metal bath is first charged with carbon to a high degree. This is effected by charging in coal, coke, graphite, or charcoal, but preferably the latter, and then scrap or pig iron on top of it. As the metal melts it takes up the carbon, the process being then carried on as usual. In the basic process a good deal of the carbon is eliminated along with the phosphorus, but sufficient remains to enable the charge to be "boiled down" with ore in a manner similar to the boiling down of a charge of pig in a siliceous-lined furnace. In this way any percentage of carbon may be obtained within certain limits, whereas with the ordinary basic process it is difficult to obtain a percentage higher than 0.15. It is generally believed that phosphorus will not leave iron in the presence of carbon, but the author has found this opinion to be erroneous.

—H. K. T.

Improvements in the Construction of Furnaces for Puddling or Heating, and other Purposes. H. R. Haigh, Derby. Eng. Pat. 20,415, December 15, 1890. 6d.

THESE improvements consist in the supply of hot air to the furnace fire, the air deriving its heat from the walls of the furnace. For this purpose an outer casing of brick or suitable metal is constructed round the sides and crown of the furnace, and air is allowed to enter through convenient openings in this casing, circulate round the furnace one or more times until it becomes highly heated, and pass into the interior of the furnace through openings constructed in the crown of the furnace near the bridge.—S. B. A. A.

New or Improved Manufacture of Articles of Nickel and of Nickel-Plated Goods. L. Mond, Northwich. Eng. Pat. 21,025, December 24, 1890. 6d.

ARTICLES of nickel are manufactured by the new process by exposing suitable moulds in the heated state to the action of the vapour or solution of nickel carbon oxide and detaching the deposit of nickel when of sufficient thickness. An adhesive coating of nickel is similarly deposited upon articles by the action of nickel carbon oxide.

The process is conveniently carried out as follows:—A cast-iron cylinder capable of rotating about its axis and fitted internally with a number of longitudinal ribs or projections is partly filled with oxide of nickel, heated to 400° C., and a current of water-gas passed in until the nickel has been reduced. The cylinder and contents are then allowed to cool down to the ordinary temperature and a current of carbon monoxide (prepared by passing carbonic anhydride over coke) is led through the cylinder into an air-tight cast-iron chamber filled with water-gas, on the bottom of which the moulds are disposed and heated from underneath to 200° C.; the gas is then led back into the cylinder, a constant circulation of the gas being kept up by a fan or other device. In its passage through the cylinder the gas takes up nickel, which is subsequently decomposed by the heated goods and wholly or partly deposited on them. On passing through the cylinder the gas is again charged with the nickel compound. After a time the nickel is less readily taken up by the gas, but its activity may be restored by heating the cylinder to 350° C. and then cooling down to the ordinary temperature, the current of carbon monoxide being maintained during the interval. Before their introduction into the chamber the moulds are coated with graphite or other substance to which nickel does not adhere; to obtain coherent deposits, air must be carefully excluded from the chamber, intermediate layers of oxide

being otherwise formed. Iron and other goods on which a particularly firm coating of nickel is required are preferably tinned in the first instance, and the nickel deposited upon them at a temperature higher than the melting point of tin, the nickel being thus practically soldered to the article. The temperature must not, however, exceed 300° C., or the deposit becomes pulverulent. It is advantageous to heat these goods in a current of hydrogen to about 400° before removing them from the chamber, as the nickel is rendered very ductile by this treatment.

Nickel may also be deposited upon articles by immersing them in liquid nickel carbon oxide or in a petroleum or benzene solution, or by sprinkling the latter on them. The deposit forms at a lower temperature (60°–70° C.), but is less white in colour than that obtained from the gas. Gases containing less than 5 per cent. of the nickel compound give a more uniform deposit than when more heavily charged.

Utilisation of Refuse or Scoria of Copper - Smelting Furnaces as a Grinding or Polishing Agent, or as a Substitute for Emery. E. A. Bath, Sketty. Eng. Pat. 21,234, December 30, 1890. 4d.

THE refuse or scoria of copper furnaces is sorted and the pieces ground in any suitable manner, this operation being followed by elutriation if necessary. The polishing powder so obtained may be used as such, or it may be mixed with glue dissolved in methylated spirit and acid, or with any other cement, and cast into blocks or wheels, or the polishing powder may be fixed to paper or linen by means of glue, &c.

—H. K. T.

Improved Fusible Mass for Case-hardening Purposes. T. Langer, Nimbürg, Austria. Eng. Pat. 210, January 5, 1891. 6d.

THE addition of borax to known case-hardening mixtures is particularly claimed, and the following proportions are given as the most advantageous:—

I.	
	Parts.
Common salt	71.4
Yellow prussiate of potash.....	23.8
Borax.....	4.8

II.	
	Parts.
Common salt	66.15
Yellow prussiate of potash.....	22.15
Carbonised horn dust.....	7.35
Borax	4.45

III.	
Common salt	About 10 parts by weight.
Yellow prussiate of potash	About 3 parts by weight.
Borax	About 2 parts by weight.
Sugar.....	About 0.2 parts by weight.

The borax (which may be replaced by some borate or silicate, as for instance powdered glass) assists the carburisation of the iron by keeping the surface free from oxide and preventing the access of air. Mixture II. produces a steel coating of a rather coarser grain than No. I., but is cheaper. No. III. gives a much tougher coating than the others; it yields a steel coating $\frac{1}{2}$ to 1 mm. thick in about two hours in an ordinary forge. The thickness of the coating may be increased by adding about one-seventh of the original quantity of the mixture employed every half-hour. The objects to be hardened should be heated to a blue heat in a charcoal fire before being immersed in the case, and the mixture should also be previously heated to the point of fusion.—S. B. A. A.

Improvements in the Manufacture of Aluminium. E. Meyer, Berlin, Germany. Eng. Pat. 1785, January 31, 1891. 4d.

According to the inventor, metallic aluminium is produced when a mixture of an aluminate of an alkali or alkaline earth with carbon is smelted in a reducing flame, the following reactions being alleged to occur:—

An Improved Process and Apparatus for Desilverising Lead. E. Edwards, London. From E. Honold, Stolberg, Germany. Eng. Pat. 2049, February 4, 1891. 8d.

This is an apparatus in which lead is desilverised by treatment with zinc. The most important part of the apparatus is shown in the Figure. The lead to be treated is delivered into B, passes under the partition R, and then

AN IMPROVED APPARATUS FOR DESILVERISING LEAD.

over the top of P, and in so doing passes through a quantity of molten zinc represented by the vertical lines. It then passes through the channel B' into the trough G, which is protected from the furnace H. Here the lead becomes cooled, and the zinc which it contains separates and solidifies on the top; the still molten lead passes round the end of the partition J, and is led to a second apparatus, where it undergoes a treatment similar to the above. It is finally received into a pan and treated with steam, which passing through the hot lead oxidises the remainder of the zinc, antimony, and other impurities, which are removed. The silver is separated from the zinc in the usual way.—R. K. T.

An Improved Method or Process for the Production of Refined Copper. C. James, Swansea. Eng. Pat. 11,337, July 3, 1891. 6d.

According to this invention the operation of treating the rich regulus (white metal) in a "roaster furnace" for purple or blister copper previous to refining is replaced by a calcination so conducted that quantities of sulphur and oxygen are left in the calcined charge in the proportions necessary for the formation of sulphurous anhydride. The matte is crushed through a sieve, or smaller, if convenient, calcined in the way proposed in any ordinary calciner, and then taken directly to the refining furnace. Mattes poor in copper may after calcination be made into bricks with clay, &c., and run down in a cupola, the resulting metal being either cast into ingots, &c., or further refined.

Poor refractory precipitates may be advantageously treated by mixing with a corresponding portion of raw matte, calcining the mixture until sulphur and oxygen are present in the requisite proportions, and refining the product.

The reaction of the sulphur and oxygen in the charge when melted in the refinery furnace eliminates nearly all the impurities (especially the volatile ones, arsenic, antimony, bismuth, &c.) usually found in poor precipitates. The non-volatile impurities are got rid of by arranging that the oxide of copper shall predominate in the calcined charge. The inventor claims that by the above process "more copper is at once obtained in a saleable form at less than a third of the usual cost, that the expense of re-working the roaster slag is dispensed with, and that the locking up of large amounts of capital in roaster furnaces and bottoms is entirely avoided."—S. B. A. A.

Improvements in Ore-Sampling Machines. H. Le Roy, Bridgman, Blue Island, U.S.A. Eng. Pat. 13,198, August 4, 1891. 8d.

See under I., page 990.

An Improved Method of Treating Plumbiferous Copper "Mattes" and Ores. C. James, Swansea. Eng. Pat. 13,739, August 14, 1891. 4d.

PLUMBIFEROUS copper mattes containing 15 per cent. of lead and upwards are now generally treated by melting them in a specially constructed reverberatory furnace, and treating with metallic iron, by which means about one half of the lead is reduced to the metallic state. The resulting copper regulus still contains from 8 to 12 per cent. of lead, which is entirely lost, as is also the whole of the lead in mattes originally containing less than 15 per cent. of that metal, these products not being capable of economic treatment by the above process, and requiring to be gradually mixed in small quantities with other material, and smelted in the ordinary way.

The inventor proposes the following process for the recovery of the whole of the lead and the separation of the copper in a pure form: The matte is crushed and partially calcined, preferably in a revolving calciner, the object being to convert the whole of the lead and iron into oxides, and to leave sulphur enough to combine with the whole of the copper. The partially calcined matte is then mixed with silica, a siliceous ore, or a highly siliceous slag, &c., and melted when the copper combines with the sulphur, and forms a rich regulus (white metal) almost free from lead, and containing nearly all the gold and silver (if those metals were originally present), whilst the slag consists of a double silicate of iron and lead, from which the latter metal may be extracted by the usual methods.

The proportion of silica to be added will entirely depend upon the percentage of lead and iron in the matte, the object being to form a double silicate.—S. B. A. A.

PATENTS.

Improvements in Galvanic Dry Elements. C. Smith, London. Eng. Pat. 1306, January 24, 1890. Amended July 15, 1891. 6d.

A zinc pot as positive electrode contains a tubular carbon with the depolarising substance held on its outer surface by a canvas wrapping. The space between the zinc and

the wrapped-up carbon is filled with the electrolyte containing a small amount of a slimy substance, such as tragacanth slime, mixed with plaster of Paris. The interior of the tubular carbon is filled with some absorbent material, such as slag wool impregnated with a saline solution. The top of the tubular carbon is closed by a carbon plug with a terminal attached. The outer vessel is closed first with plaster of Paris, and over all with pitch. Any gases generated have to travel a short distance through plaster of Paris to holes near the top of the zinc pot, where they escape into a casing containing the whole cell. The space between the casing and the zinc is filled with sawdust or other absorbent material.

The amendment seems to consist in the deletion of a contradictory sentence in the text.—E. T.

An Improved Artificial Asphalt. H. P. and E. G. Williams, London. Eng. Pat. 13,595, August 29, 1890. 4d.

See under IX., page 1008.

Improvements in the Manufacture of Electrical Insulating Materials. J. R. Thame, London. Eng. Pat. 16,747, October 21, 1890. 4d.

THE improved insulating material is made from pure or nearly pure cellulose, with which are incorporated gums, drying oils, or resins. When the material is intended to replace slate, it is made by mixing together slate dust, drying oils, or resins and silicate of potash, the mass being slowly dried and heated to redness.—E. J. B.

An Improvement in Mercury Vacuum Pumps. E. C. C. Baly, London. Eng. Pat. 20,309, December 12, 1890. 6d.

See under XXIII., page 1032.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

On a Nitrogenous Substance in Train Oil. W. Fahrion. Zeits. f. angew. Chem. 1891, 416—148. (See also this Journal, 1891, 557.)

JAHODA (Zeits. f. angew. Chem. 1891, 325) finds a nitrogenous substance, insoluble in petroleum ether, to be contained in train oil and in *dégras*; the same is likewise insoluble in ether. The author still upholds that this substance is an impurity, for he himself has been able to recognise the presence of a nitrogenous body, but only in dark-coloured masses, which were found at the bottom of a vessel containing train oil several years old. He considers that such "impurity" has its origin in the skin of the fish.

At the same time, it is to be remembered that Gautier and Mourgues have found various nitrogenous substances, chiefly amines, in blubber (Compt. Rend. 107, 110, 254, 626 and 743).—T. L. B.

Glycerin. J. Schenkel. Zeits. f. angew. Chem. 1891, 505—508.

THE author points out that, although glycerin is used in many industries, by far the largest quantity of it is consumed in the production of nitroglycerin. The following figures show the rapid increase in the manufacture of dynamite. There was produced in—

1868 about 220 cwt. of dynamite.
1870 about 8,500 cwt. of dynamite.
1873 about 41,000 cwt. of dynamite.
1874 about 62,000 cwt. of dynamite.
1876 about 100,000 cwt. of dynamite.

and for 1886 the quantity is estimated to have been at least 10,000 tons. The large consumption of glycerin in this industry encouraged the adoption of processes for its recovery in the soap and candle manufacture, and the waste liquors are now everywhere worked up for the glycerin contained in them. Two general methods are in use: 1. The splitting up of the fats at a high temperature and pressure, whereby fatty acids and glycerin are produced; and 2. The saponification of fats by alkalis for the production of soap from the lyes, of which the glycerin is recovered by evaporation. The crude glycerin obtained by these methods requires to be distilled in order to purify it sufficiently for most of its uses. According to French journals a good and practical process has been invented enabling soap-makers to recover the whole of the glycerin in a nearly pure condition in a cheap and simple apparatus, but at present the method is kept secret. The author mentions a universal complaint by the glycerin producers against the unreasoning stringency of the German official test for the purity of glycerin for pharmaceutical purposes, which requires that 1 cc. of glycerin heated to boiling with 1 cc. of ammonia solution and three drops of silver nitrate solution must give neither colour or precipitate within five minutes. The author states that it has not been possible to prepare glycerin capable of passing the prescribed tests, and the matter is being officially investigated by the German Office of Health in the interests of all concerned. The following table shows the relative production of glycerin in the countries of the world:—

	From the Stearin Manufacture.	From the Soap Manufacture.
	Tons.	Tons.
France	6,000	3,500
Germany	3,000	2,000
United States	3,000	3,000
Netherlands	2,000
Austria	2,000
Russia	2,000
Belgium	1,800
Italy	1,800
England	1,200	5,500
Spain	1,500
Sweden and Norway	350
Switzerland	300
Argentina	300
Australia	300
Portugal	200
Roumania	150
Greece	100

The principal commercial centre for glycerin is Paris. The price of glycerin has been subject to great fluctuations and varied between 35 fr. and 205 fr. for 100 kilos, crude

glycerin from 1861 to the present time, at which the price fluctuates between 50 and 100 fr. The want of steadiness in the value of glycerin is a source of great difficulty to the refiner.—W. M.

The Determination of Unsaponifiable Matter in Fats. M. Honig and G. Spitz. *Zeits. f. angew. Chem.* 1891, 565—568.

See under XXIII., page 1039.

The Valuation of Lubricating Materials with Special Reference to Petroff's Process. A. Künkler. *Dingl. Polyt. J.* 1891, 231, 297—300.

It is the author's opinion the various criteria, and the apparatus described by Lew (*Dingl. Polyt. J.* 280, 16 and 10; this *Journal*, 1891, 777), which form Petroff's method for examining lubricating materials, are to a large extent valueless, owing to a mistaken idea as to the true part played by a theoretically perfect lubricator. Of all properties necessary for efficient lubrication, by far the most important is that the oil or grease should possess sufficient capillarity or adhesion (*Schleppfrigkeit*), while considered from the purely theoretical standpoint the lower the viscosity or cohesion, the smaller the internal friction and therefore better the material. The external friction is partly a factor of this latter, being smaller when the viscosity is high, but at the same time it is dependent on the adhesion varying with it; its amount, however, is a matter of little consequence.

Considering the matter from the economical point of view, it is evident that what is required is that the lubricating material possess sufficient adhesion to prevent contact of the metallic surfaces, and also that the viscosity be as high as possible without increasing too much the internal friction, so that the amount consumed may be as small as possible; and yet the power required for driving not increased. Hence it may be seen that under different circumstances different oils are preferable, so that whilst rape oil is absolutely a better lubricating material than a Russian mineral oil of sp. gr. 0.908—1.0 whose viscosity at 40° C. is double the former, yet at a low speed with a moderate load and a high temperature the latter is more economical in use; but if the load be increased sufficiently, a point will be reached when the adhesion of the mineral oil is overcome, so that it is rendered useless, while the rape oil will still continue to act efficiently.

The adhesion of the lubricating material being the most important factor to be considered, and the various machines in use for testing oils, indicating only the viscosity, these become of little or no value; they help one to choose between two oils of the same class, but even then their indications are uncertain, Petroff's apparatus being no better than the simpler forms. The choice of a lubricator must therefore be left to experience, from which we know that the majority of vegetable and animal oils employed possess far more adhesion than mineral oils, and that these latter when of the same colour, *i.e.*, the same degree of purification, are the more adhesive the more viscid they are. It is this latter fact that has given rise to the viscosimeters, and hence it is evident that they must be strictly kept for the testing of mineral oils. While in the case of these oils the internal friction increases with the adhesion and the viscosity, they cannot be compared as lubricating materials with rape oil by means of this factor, as is done in Petroff's method, with the idea that they are the more suitable for lubrication, the closer they resemble the curve of the internal friction of rape oil, as exactly the reverse is the case, for the greater the internal friction of a mineral oil, the more its curve differs from that of rape oil, and yet the more able are their lubricating properties.—E. H. L.

Analysis of Russian Waxes. J. Antoushevich. *J. Russ. Chem. Soc.* 1891, 23, 223—235.

The author has had opportunity to study a great variety of pure waxes brought from all parts of Russia and Siberia. The results obtained by him are as follows:—

The pure wax is entirely soluble in chloroform, turpentine, carbon bisulphide, and only partially soluble in alcohol, ether, petroleum ether, and benzene. The specific gravity of yellow wax is 0.956—0.964, and that of white 0.969. The melting point of yellow wax, 60°—65°; of white, 65°—70°, but the purity of the wax cannot be deduced from this property.

Since the specimens of wax were undoubtedly quite pure, the author has undertaken to analyse them in order to decide whether Russian wax is identical with the Austrian product.

This method proposed by Becker (*Dingl. Polyt. J.* 234, 79; *ibid.* 249, 383; this *Journal*, 1883, 418), consists in neutralising the acid of the wax with alcoholic solution of caustic potash, in order to determine the acidity of the wax in mgrms. of the caustic potash used per 1 grm. of wax; and further, it consists in boiling the melted wax with six times its weight of caustic potash for one hour, in order to determine in mgrms. of caustic potash used the amount of ether contained in 1 grm. of wax. Having obtained both these figures the saponification value can be determined, and also the ratio of the acid to the ether in the wax. Whilst using this method the author has found that it is absolutely necessary to boil the wax with water previous to analysing it, in order to get rid of the glucose of honey always present.

Besides, it has been found that one hour's boiling of wax with caustic potash, as suggested by Gueble, is far from being sufficient to complete the saponification of the ether; at least two boilings of two hours' duration each with fresh caustic potash are necessary. Under these conditions of analysis the Russian and Austrian waxes are found to be identical.

	Pure Russian Waxes.	Pure Austrian Waxes by Gueble.
Acidity	19—21	19—21
Ether value.....	70—77	73—76
Saponification value.	92°—97°	92°—97°
Ratio	1:3.6—1:3.8	1:3.6—1:3.8

The ratio higher than 3.8 indicates admixture of tallow or Japanese or Carnauba wax. The ratio below 3.6 indicates the presence of stearic acid or tar. The point of saponification below 92° (the ratio being regular) indicates the presence of paraffin or ceresin.—N. W. T.

An Improved Soap Powder. W. Wright, Droylsden. Eng. Pat. 16,579, October 18, 1890. 4d.

The patentee mixes and powders common bar soap with concentrated soda, the latter being pure dry carbonate of soda, not containing free caustic soda.—K. E. M.

A Process for Bleaching Palm-oil and other Vegetable Oils. E. Hermite, E. J. Patterson, and C. F. Cooper, London. Eng. Pat. 17,160, October 27, 1890. 4d.

PALM oil and other vegetable oils are bleached by agitating them in a steam-jacketed vessel with "electrolysed

chlorides" such as a mixture of magnesium chloride with sea salt. It is preferable to electrolyse the chlorides before being mixed with the oils. (See also Eng. Pat. 1993 of 1887; this Journal, 1888, 126).—K. E. M.

Improvements in the Treatment of Soapmakers' Waste Lyes for the Recovery of Glycerin and other Substances. J. Taylor, Leith. Eng. Pat. 19,382, November 28, 1890. 4d.

BOILING "soapmakers' waste lye" is neutralised with bisulphate of soda (nitre cake). After saturation with either alkali or sulphate of soda, or after adding an excess of bisulphate of soda and neutralising with carbonate of lime, the liquor is allowed to cool in order to separate out the soda salts. The mother-liquor is treated in the usual way for recovering the glycerin and sodium chloride.

—K. E. M.

A Washing Jelly. A. R. Waddell, Airdrie. Eng. Pat. 19,830, December 5, 1890. 4d.

To $\frac{1}{2}$ lb. of soap, preferably soda soap, dissolved in 1 lb. of boiling water, add 1 oz. of turpentine, and before this mixture has set by cooling, stir in 1 oz. of strong liquid ammonia. The resulting compound, when cold, forms a jelly which may be rendered more homogeneous by repeating and allowing to cool a second time.—K. E. M.

Improvements in the Manufacture and Production of Saponaceous Matter, applicable for Use in or connected with the Dyeing of Textile Fabrics or Materials and for other Purposes. C. E. Maistre and J. M. Campagne, Paris, France. Eng. Pat. 21,062, December 24, 1890. 8d.

THE specification describes the recovery of unfixed indigo on textile materials by the use of a specially-prepared soap solution in the indigo dyeing-vat. The soap solution may also be used for cleaning and scouring textile materials, skins, &c., as well as for oiling wool. The soap is obtained by mixing solutions of sulphhydrate of soda, caustic soda, and carbonate of soda with oleine in suitable proportions.

—K. E. M.

Improvements in Apparatus for Purifying Waste Oil. O. K. Thomasseu, Christiania, Norway. Eng. Pat. 14,365, August 25, 1891. 6d.

WASTE oil such as collects in the drip-cups under bearings is filtered by an apparatus consisting of three cylindrical vessels loosely placed upon one another. The oil passes through a fine then a coarse iron-wire gauze, between which a layer of cotton wool is placed, secured by means of a conical ring. After filtering through two more sieves of similar construction but made of flannel or other suitable material and placed vertically, the oil is conducted by means of wicks through a number of pipes passing through the bottom of the second vessel to the lowest one. A drawing of the apparatus accompanies the specification.

The Examination of Linseed-Oil Varnish. W. Fahrion. Zeits. f. angew. Chem. 1891, 540.

THIS process for examining the degree of boiling, to which the linseed oil has been subjected, depends on the fact that the unsaturated fatty acids yield on oxidation oxy-fatty acids which are insoluble in petroleum ether, while the unoxidised acids as well as the products of the oxidation of the saturated fatty acids are soluble. It is in all probability the linolenic and iso-linolenic acids (Hazura, Zeits. f. angew. Chem. 1888, 315; this Journal, 1888, 506 and 681) which are first attacked on boiling, and seeing that these substances make up 80 per cent. of the total unsaturated fatty acids present in linseed oil, the oxy-fatty acids contained in the varnish must consist in great measure of their derivatives.

In a porcelain basin of a capacity of about 150 cc., 3—5 grms. of the varnish are saponified with 15—25 cc. of 8 per cent. alcoholic soda with continual stirring. When the alcohol has been driven off, the soap is dissolved in 50—70 cc. of hot water and washed into a separating funnel of 500 cc. capacity. Dilute hydrochloric acid is then added, and after cooling 100 cc. of petroleum ether (distilling below 80°), after thorough shaking, the whole is left at rest for an hour till the petroleum has become clear. The aqueous liquid is run off, when the oxy-acids will be found sticking to the walls of the funnel, so that the petroleum can be poured away without filtering. After washing two or three times, the acids are dissolved in a small quantity of warm alcohol and the solution evaporated in a tared basin and the residue dried for one hour at 100—105°. In different kinds of varnishes the author has found from 0.6 to 31.6 per cent. of oxy-acids; prepared in large quantities, they form a thick, dark-red oil, completely soluble both in alcohol and ether. The author hopes to continue his researches on these substances.—F. H. L.

Colour-Photometry. Captain Abney. Proc. Chem. Soc. November 19, 1891.

PATENTS.

Improvements in obtaining White Compounds of Lead and Zinc suitable for Making Pigments, and for other Purposes, from Lead and Zinc Ores or from their Products or Residues and in Apparatus therefor. A. French, Morriston. Eng. Pat. 2494, June 8, 1881. (Second Edition.) 8d.

THE inventor claims "the process for producing white compounds or pigments composed of sulphite of lead and sulphite of zinc, in which process calcined ores or materials containing lead and zinc are partly reduced and partly sublimed in a cupola smelting furnace, air being introduced amongst the volatile matters above the charge as well as at the tuyere, combined with the use of a wet condenser in which the sublimate is collected and simultaneously purified by means of water."

For details of the apparatus the specification must be consulted.—O. H.

Improvements in the Preparation of Rapidly Drying Resinous and other Oils or Varnishes. G. M. Cruikshank, Glasgow. From E. Pietzcker, Hamburg, Germany. Eng. Pat. 12,123, August 2, 1890. *Id.*

THE patentee claims "the preparation of rapidly drying resins and other oils or varnishes, consisting in dissolving in the oil resin, a dryer, and in treating the oil with one of the following sulphur compounds," sulphite, hyposulphite, and "sulphuret of potash, sodium ammonia, strontium, baryta, calcium."—O. H.

An Improved Material for Use as a Substitute for Gutta-Percha, Rubber, Oiled and other Transparent Tissues, and for other Purposes. T. Christy, London. Eng. Pat. 12,230, August 5, 1890. *Id.*

THIS invention consists of further improvements in the manufacture of a material, "Christia," described in Eng. Pat. 13,917 of 1888 (this Journal, 1889, 992). The chief ingredients used are gelatin, glycerin, chromic salts, preferably potassium bichromate, and antiseptics, such as ammonium sulphite.

Methods are described for the production of waterproof and fireproof material, very full details of which are given in the specification.—E. G. C.

Improved Blacking for Leather. J. P. Bayly, London. From J. Bauleh, St. Louis, U.S.A. Eng. Pat. 15,561, October 1, 1890. *Id.*

THIS waterproof compound consists of two parts by weight of beeswax, four of neat's foot oil, one and a half parts of drop black, two of heel-ball, and one part of molasses.

The combination so produced is stated to be especially suited for harness, &c.—E. G. C.

Improvements in Compounds to be Used in Vulcanizing Rubber and other Substances or Compounds. C. A. Fawcitt, Glasgow. Eng. Pat. 17,197, October 28, 1890. *Id.*

WHEN iodide or bromide of antimony or the bromide or iodide of certain other metals is intimately mixed with the sulphur to be used for the vulcanising or "curing" process, better results are obtained, and in the case of the waterproofing of woven fabrics, the rubber compound may be made more or less transparent so as not to greatly obscure the colour or texture of the fabric. In some cases it is found advantageous to add a small quantity of aniline or suitable organic base to the other ingredients, and instead of sulphur a sulphide, thiosulphate, thiocarbonate, or organic sulphide may be used.—O. H.

Process for Obtaining a New Material from Bituminous Slates, and its Application as a Filtering Medium and as a Colouring Matter. J. Zeller, Elbingen, Germany. Eng. Pat. 17,218, October 28, 1890. *Id.*

Improvements in the Manufacture of Waterproof Garments, and in Apparatus Employed thereon. I. Frankenburg, Salford. Eng. Pat. 18,216, November 12, 1890. *Id.*

THE inventor claims "the use and application of a steam-pipe trough or chest flat on the top supplied with steam or its equivalent heating medium fitted in and level with the surface of a table for the use of operatives engaged in coating and cementing waterproof garments."—O. H.

Process and Apparatus for the Manufacture of Ultramarine. O. Murray, London. From the Firm of "Julius Curtius," Duisberg, Germany. Eng. Pat. 18,527, November 17, 1890. *Id.*

THE patentee describes a retort furnace for the manufacture of ultramarine, containing metal retorts lined with refractory material, and suitably connected with a common cooling and oxidising chamber and absorption vessels. The refractory material consists preferably of so-called "refractory cement," or silicate of alumina, coke, graphite, &c., "cemented together with carbonisable cementitious substances, such as dextrine, syrup, and the like."—O. H.

Improvements in the Preparation of Pigments or Colouring Compounds. W. Grimshaw, Manchester. Eng. Pat. 4334, March 11, 1891. *Id.*

THIS invention consists in the admixture of glucose, glycerin, &c., with pigments for the purpose of bringing the colours into a suitable condition for blending easily with water, or thick and semi-pasty substances, such as starch, flour, or gum.—E. G. C.

Improvements in the Manufacture of White Lead. H. H. Lake. From C. W. Dahl, New York, U.S.A. Eng. Pat. 8161, May 12, 1891. *Id.*

A SOLUTION of basic and neutral lead acetates, prepared by exposing metallic lead to the successive action of dilute acetic acid and air, is precipitated as basic carbonate of lead by means of a carbonate of an alkali.

The patentee also claims the use of "dilute acetic acid and hot air," and the use of "hot diluted acetic acid and hot air;" for details the specification must be consulted.

—E. G. C.

Improved Process of Manufacturing Lead Sulphate from Metallic Lead. H. Pennington, Chicago, U.S.A. Eng. Pat. 8510, May 19, 1891. *Id.*

THIS inventor claims, by the modifications introduced by him into the method of treatment of the lead with acetic acid and air, and afterwards with sulphuric acid, to produce an amorphous, dense, and superior form of lead pigment. The lead is kept in a loose condition "by suspending it between downwardly converging supports during the acetation and aeration," in a "frusto-conical or tapering polyhedral" vat or "corroder;" and in the sulphating tank the solution is subjected to the action of a mechanical agitator.—E. G. C.

Improvements in Cleaning Kauri Gum. J. C. Firth, Auckland, New Zealand. Eng. Pat. 9115, May 29, 1891. *Id.*

THE pieces of Kauri gum are subjected to a "revolving, rotating, or reciprocating action in a cylinder, into which is introduced granulated scoria, pumice, silver sand, and a variety of other cleaning materials."—E. G. C.

A Method of and Apparatus for the Purifying of Gutta-Percha. R. Haddon, London. Eng. Pat. 9231, June 1, 1891. *Id.*

THE crude or raw gutta-percha is treated with bisulphide of carbon in a suitable agitating vessel. The solution is run off from the foreign insoluble matters, such as earthy matter, sand, &c., into depositing vessels, where the heavier solution of oxidised gutta-percha separates below the lighter solution of unoxidised gutta-percha. The latter solution is then removed, and the carbon bisulphide distilled off, leaving a residue of "pure gutta-percha containing however still some resinous matter."

Carbonic oxide is passed into the vessel containing the solution of oxidised gutta-percha to reduce the latter, which,

after evaporation of the solvent, is mixed with the residue of pure gutta-percha, and the mixture treated with "benzine, or essence of thérébentine, or any other essential oil which dissolves resin." The solutions are treated as described above, and evaporated for the recovery of the solvents. Instead of mixing the deoxidised product with the pure gutta-percha, it may be treated separately for the removal of the resin and to form a product of secondary quality.—O. H.

Improved Manufacture of Hard Natural Resins as Substitutes for Natural Resins, such as Copal, Amber, and the like. H. Beck, London. From E. Schaal, Fuerbach, Germany. Eng. Pat. 9747, June 9, 1891. 4d.

CRUDE or purified resin acids are combined with "equivalent proportions of mixtures of alcohols (especially glycerol, phenols, sugar), and metallic oxides."—E. G. C.

An Improvement in the Manufacture of India-Rubber. A. J. Rath, Hyde. Eng. Pat. 10,524, June 20, 1891. 4d.

GREATER toughness, strength, and durability are imparted to the india-rubber by the admixture with it, while in the state known as "dough," of a small proportion of fibres of waste silk.

The product thus obtained is said to be particularly adapted for protecting "pneumatic" cycle tyres, "noiseless tyres," &c. of vehicles.—E. G. C.

Improved Process of Devulcanising Vulcanised India-rubber, Gutta-Percha, and similar Gums, and Reclaiming the Rubber therefrom for Re-manufacture without the Addition of Pure Rubber. A. F. B. Gomess, London. Eng. Pat. 10,528, June 20, 1891. 4d.

THE rubber is first boiled with an alkaline carbonate, sulphite, or hydrate. It is then washed and treated with dilute sulphuric acid and cast iron scrap. After being allowed to remain for a time in a dark place, the rubber is removed, treated with a solution of caustic alkali, washed again, and the last-described operation repeated till the sulphur has been removed.—E. G. C.

Improvements in Anti-Fouling and Anti-Corrosive Compounds for Ships' Bottoms and other Purposes. M. E. Dejeune, Stapleton, U.S.A. Eng. Pat. 13,513, August 11, 1891. 4d.

THE composition employed consists of fine zinc dust (6 parts) and paraffin wax (1 part). The paraffin wax is simply used as a binder; the mixture is applied hot and scrubbed in.

—O. H.

Composition of Matter for Waterproofing Pulp and other Fibrous Articles. J. C. Chapman, London. From the "United Indurated Fibre Company," Portland, U.S.A. Eng. Pat. 14,272, August 24, 1891. 4d.

THE high cost of waterproofing, when linseed oil alone is used for this purpose, and the objectionably brittle character of a mixture consisting of linseed oil and resin are obviated by the substitution of a compound containing linseed oil, resin, and cotton-seed oil. The latter softens the resin and frees it from brittleness. In order to facilitate the operation of mixing the resin may be dissolved in naphtha. The entire mixture is heated to about 150° F., when the ware, after being soaked in it, is allowed to stand in the air in order to volatilise most of the naphtha and then baked at a temperature of 250° F., until the mixture is oxidised throughout.—K. E. M.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENT.

A New or Improved Method and Apparatus for Shrinking Leather by means of Fat. J. de Hessel, Duesseldorf, Germany. Eng. Pat. 15,661, September 15, 1891. 6d.

THIS invention relates to an apparatus in which leather may be "shrunk" with fat, without the danger of over-heating which accompanies the methods hitherto employed.

Two concentric metal cylinders, capable of revolving on axial trunnions, are constructed of such relative diameter that an annular space between them may serve for the circulation of the heating liquid, such circulation being ensured by a rib wound helically round the outside of the inner or stuffing chamber. The outer cylinder is covered, and the inner cylinder lined, with wood. The circulating heating liquid is introduced by pipes through one of the trunnions. The other trunnion is hollow, is in direct communication with the stuffing chamber, and contains a thermometer, whose indication must be carefully watched through a glass window in the wall of the trunnion. The leather and fat are introduced into the inner chamber through a man-hole and revolution is maintained throughout the process.—A. G. B.

XV.—MANURES, Etc.

Absorption of Ammoniacal Nitrogen by certain Plants.

A. B. Griffiths. Chem. News, 1891, 64, 147.

IN the author's experiments, bean seedlings, previously immersed 30 minutes in a solution of copper sulphate to destroy all nitrifying organisms, and washed in sterilised distilled water, were supported on pieces of cork in sterilised glass vessels containing sterilised solution composed of:—

Distilled water	1,000 cc.
Potassium chloride	1'00 grm.
Ferrous carbonate	0'03 "
Sodium chloride	0'50 "
Calcium sulphate	0'50 "
Magnesium sulphate	0'50 "
Tricalcium phosphate	0'50 "
Ammonium sulphate	0'50 "

Each glass vessel being placed under a sterilised bell-jar closed below by a glass plate and above by a sterilised cotton wool plug. Under these circumstances, with only ammoniacal nitrogen supplied and nitrification impossible, the beans grew well for four weeks, without developing any nodules indicative of absorption of atmospheric nitrogen. At the end of the experiments the solutions were free from nitric nitrogen, but the ammonium sulphate was reduced from 0'050 to 0'027 per cent. These results indicate that nitrogen was absorbed as ammoniacal nitrogen by the roots of the plants.—D. A. L.

Ammonium Phosphate as a Manure. J. H. Vogel. Zeits. f. angew. Chem. 1891, 568-573.

THE investigation arose out of an attempt to ascertain whether the use of the two most valuable ingredients in artificial manures, namely, nitrogen and phosphoric acid, combined in the form of ammonium phosphate, was commercially practicable. In the course of this work experiments were made to compare the manurial effect of ammonium phosphate with that of an equivalent mixture of sulphate of ammonia and superphosphate; as much gypsum as was present in the superphosphate used, was added to

the ammonium phosphate to make the result strictly comparable, a precaution the more necessary inasmuch as the soil experimented with was poor in lime. Contrary to expectation the effect of the ammonium phosphate was found to be less favourable than that of the superphosphate mixture, the inferiority being increased rather than diminished by the addition of gypsum. Under these circumstances it was decided to examine the action of calcium sulphate upon ammonium phosphate in order to throw light upon the results observed. The method adopted was as follows: Ammonium phosphate and calcium sulphate were digested with water in a litre flask, filtered, and the salts present in the filtrate determined. They might comprise ammonia, phosphoric acid, sulphuric acid and lime; the same bodies might be present in the residue with the exception of ammonia. Starting on this assumption the author has made a large number of analytical observations on the composition of the filtrate and the insoluble residue, and has obtained results that lead him to consider that the decomposition occurs in the manner represented by the following equations:—

I.

II.

from which it is plain that calcium sulphate at the ordinary temperature, and in contact with water, acts upon ammonium dihydrogen phosphate with the production of the corresponding calcium salt, and similarly when diammonium hydrogen phosphate is used calcium monohydrogen phosphate is formed. The like is true with neutral ammonium phosphate. The practical deduction from these results is that only ammonium dihydrogen phosphate should be used as a manure when gypsum has to be added to the soil, as is commonly the case. The possible proportion which ammonium can advantageously bear to phosphoric acid is therefore comparatively low.—B. B.

The Phosphates of Algeria and Tunis. Eng. and Mining J. October 31, 1891, and Bull. de la Soc. Geol. de France, I, 1891.

It is significant of the interest now being taken in the deposits of phosphates of lime, that the greater part of the *Bulletin de la Société Géologique de France* for the first half of this year should be given to a description of the phosphates of Algeria and Tunis by M. Philippe Thomas, and that at the same time in the quarterly Journal of the Geological Society of England should be a paper on the phosphatic chalk at Taplow by Mr. A. Strahan, of which a brief synopsis by the present writer was printed in the *Engineering and Mining Journal* of October 31st, 1891.

These deposits recently found in Tunis and Algeria bid fair to rival those of Florida, and though they are both primarily Eocene deposits, they differ considerably in geological conditions; both, however, seem to be derived from the leaching of a phosphatic limestone. The new beds described by M. Thomas resemble very closely the deposits of Ciply in Belgium and Taplow in England, except that they seem far more extensive. They are found on the *hauts plateaux* of Tunis, and are distant about 20 kilometres from a seaport. A portion of them has been exhaustively examined by competent engineers. There are other tracts discovered but not yet thoroughly examined.

The phosphate occurs in well-defined strata, overlaid and underlaid by a more or less crystalline limestone, all tilted at an acute angle, so that the outcrop is distinct and readily traced, examined, and worked. This outcrop has been carefully examined and measured for a distance of 30 kilometres, though traced for about 60 kilometres. The beds in which the beds of phosphatic chalk occur have a thickness of from 30 to 50 metres. The richest bed had a mean width of 10 metres, and will average 50 per cent. of phosphate of lime. This, by washing, can readily be increased to 60 per cent. or 65 per cent. tricalcic phosphate, and there is an abundant and constant supply of water.

These phosphates contain less than 1 per cent. of iron and alumina and very little silica. The engineers sent by the French Geological Survey estimate that there are at least 10,000,000 tons of 60 per cent. phosphate in sight, and it is presumed that, as the strata are tilted, the deposit will continue in depth, but they have only estimated what can be extracted without machinery. A railway is projected to reach these beds. Concessions for mining them have already been secured from the Government by a French syndicate, and it is expected that very shortly active development will begin, and these phosphates placed on the market. Native unskilled labour is abundant and cheap.

MM. Tissot and Mercier, who have also examined these beds, prophesy that Tunis, which in the time of the Romans was known as the granary of the world, but which is now sterile, will regain its old fertility, as it is phosphate which has been lacking.

A great number of fossils were found and determined in the phosphate beds, and there is a large amount (8 per cent.) of organic matter present in composition. The phosphate is of a greyish to yellowish colour, with brownish pebbles, and seems to be physically identical with the deposits at Taplow and Ciply; there is the same matrix of phosphatic chalk, with fish coprolites and broken fragments of bone and teeth, fish scales, &c. The occurrence is also noted of a number of "pebbles" of a phosphatic chalk, covered with a crust of dark-coloured, resinous phosphate which seems identical with some varieties of Florida "pebble."

The discovery is very interesting, and this section will probably provide at no very distant date vast quantities of phosphate, and may prove a formidable rival to South Carolina and Florida.

XVI.—SUGAR, STARCH, GUM, Etc.

On the Chemical Nature of Barley-Gum or "Galactoxy-lum." C. Lintner and G. Düll. Zeits. f. angew. Chem. 1891, 538—539.

See under XVII., page 1019.

PATENTS.

Process for Obtaining a New Material from Bituminous Slate, and its Application as a Filtering Medium and as a Colouring Matter. J. Zeller, Esslingen, Germany. Eng. Pat. 17,218, October 28, 1890. 4d.

See under I., page 990.

An Improvement in the Manufacture of Invert Sugars. F. W. Thompson, Burton-on-Trent. Eng. Pat. 21,101, December 27, 1890. 4d.

In a previous patent (Eng. Pat. 8686 of 1884; this Journal, 1885, 291), the present inventor described a process for inverting cane sugar by yeast. The present invention relates to a means of clarifying the inverted solution. For this purpose precipitated calcium sulphate (such as is produced by neutralising with whiting the sulphuric acid used in the manufacture of glucose), is added to the solution, or calcium sulphate may be precipitated in the solution itself.

The mixture yields a perfectly clear solution, which is concentrated in the usual way.—A. L. S.

Improvements in and relating to the Automatic Discharge of Charcoal Kilns. A. Orkney, Greenock. Eng. Pat. 11,495, July 7, 1891. 6d.

The patentee describes kilns for reburning and revivifying charcoal for the clarification of sugar consisting of chambers containing a series of vertical cast-iron pipes or retorts, round which pass the hot gases from the furnace, and which communicate below with vertical iron cooling pipes from which the re-burnt charcoal is finally drawn off by an automatic discharge apparatus and stored in a suitable receiver. This invention consists in arranging beneath the cooling pipes a hopper divided into corresponding compartments from which the charcoal is discharged on to a revolving roller, past escape plates which may be adjusted either individually or collectively.—S. B. A. A.

Improvements in or connected with Filter-Press Cloths. O. D. Droop, Havannah, Cuba. Eng. Pat. 16,581, September 30, 1891. 6d.

See under I., page 991.

XVII.—BREWING, WINES, SPIRITS, Etc.

On the Chemical Nature of Barley-Gum or "Galactoxylane." C. Lintner and G. Düll. Zeits. f. angew. Chem. 1891, 538—539.

LINTNER has already described (this Journal, 1890, 1053) a semi-soluble gum which is found in barley, and which passing through all the brewing operations finally remains in the beer. Owing to the difficulties attending the preparation of the substance, experiments on its crystallisation have been unsuccessful, and it has had to be identified by conversion into osazones. Three grms. of the gum, prepared from malt and purified by two precipitations, were heated with 15 cc. of hydrochloric acid (sp. gr. 1.125) and 200 cc. of water for three hours on the water-bath, neutralised, and, after cooled, treated with yeast. No fermentation taking place, the liquid was decolourised with animal charcoal, concentrated and heated for one hour on the water-bath with about 6 grms. of phenylhydrazine acetate. The resulting osazone, after cooling, was removed by the pump and extracted with 40 per cent. alcohol. The soluble portion after repeated crystallisations gave an osazone melting at 160° and crystallising in long matted yellow needles, yielding on analysis figures agreeing with a pentose compound, the alcoholic solution of which showing no left-handed rotation, it could only be xylosazone. The portion insoluble in alcohol gave an osazone melting at 193°—194°, which proved to be galactosazone. No other substances being present, the gum may be called "galactoxylane," having the empirical formula $C_{11}H_{20}O_{10}$, with which the figures obtained on ultimate analysis agree closely.

Lippmann has already described a gum obtained from an exudation from beets, which yields on inversion galactose and arabinose (Ber. 1890, 23, 3564, this Journal, 1891, 375).—F. H. L.

PATENTS.

Improvements in or relating to Wines and Spirits. H. A. Snelling, London. Eng. Pat. 18,795, November 20, 1890. 4d.

Two oz. of either fresh or dried hops are added to one gallon of a strong wine, such as sherry, or half the quantity to a light wine, such as hock, and allowed to remain for from one to four weeks. The wine is then decanted off the hops and is said to be improved in aroma and flavour. Spirits may be treated in the same way, a larger proportion of hops being used. A small proportion of glycerin may be added with advantage in certain cases.—A. L. S.

Improvements relating to the Production of Dry Yeast, Cattle Food, and Spirit from Vegetable Products containing Starch. R. Genge, Halle, Germany; A. and D. Sigmond, Klausenburg, Hungary. Eng. Pat. 20,073, December 9, 1890. 8d.

A wort is prepared from starchy substances either by the action of malt or mineral acids. This is filtered and pitched at 20°—24° R. with dry yeast. Air is blown through the wort as it ferments, the air having been previously purified by passing through a strong mineral acid. The fermentation is complete in 8—12 hours, when the yeast is removed by either being allowed to deposit in shallow vessels or by means of centrifugal machines. The fermented liquor is distilled to obtain the alcohol.—A. L. S.

Improvements in the Production of Ferments and of Fermented Alcoholic Liquors. J. Takamine, Chicago, U.S.A. Eng. Pat. 5700, April 2, 1891. 6d.

THE cereals used to prepare "Moyashi" (either before or after being steamed) are sprinkled with a solution containing 25—35 parts K_2O , 10—30 parts CaO , 10—30 parts MgO , 50—75 parts P_2O_5 , 2—10 parts NH_3 or N ; the solution is to be made slightly alkaline, and from 1—4 per cent. is used. The ferment spores are then added, and after a little time the "Moyashi" is formed; it consists of a grain or cereal with a green mould. This is dried at a low temperature, and the grain sifted from the green powder, which consists of the ferment spores.

The ferment spores may be preserved by mixing them with some hygroscopic invert substance, such as roasted starch or anhydrous calcium sulphate.

Koji is prepared from any starchy substance by first steaming it, in order to thoroughly gelatinise the starch, allowing this to cool to 30° C., and seeding with $\frac{1}{500000}$ part pure moyashi prepared as above.

The mass is placed in a chamber ranging 20°—40° C. and after 24 hours is spread out in a thin layer, and is allowed to remain thus until the koji ferment develops. This is indicated by the formation of a white mould over the same. It is then ready for use.

The koji acts as a diastatic and alcoholic ferment.

Moto is prepared by mixing 2 parts of koji with 4—5 parts of gelatinised starch; or gelatinised starch and sugars; or malt and gelatinised starch; or malt, gelatinised starch and sugars; or malt; or malt and sugars. The mixture is ground to a soft paste, and kept at 25°—40° C. until it acquires a proper condition of maturity. The fermented liquor will contain 15—20 per cent. alcohol. There are 23 claims in the specification.—A. L. S.

Improvement in the Purification of Yeast. H. Eliot, Rotterdam, Holland. Eng. Pat. 12,668, July 25, 1891. 4d.

THE yeast is mixed with water, well shaken, passed through a sieve, and conducted into a centrifugal machine which separates the yeast from the water. The yeast is obtained in a pasty mass. This treatment is said to render beer yeast suitable for baking purposes.—A. L. S.

A Process and Apparatus for the Production of Sparkling Wines and other Sparkling Beverages. A. Bruns, Halle, Germany. Eng. Pat. 14,276, August 24, 1891. 8d.

THE wine is placed in a vat which is enclosed in an air tight metal envelope. The wine is seeded with a yeast, which is obtained by adding squashed raisins to a light sugared wine, and keeping the mixture in a warm place until it ferments. A little alum and tannin is added at the same time. Fermentation takes place, and the tannin and alum cause the yeast to settle in a pulverent state. When clear, the wine is bottled by means of an apparatus similar to that used in the manufacture of mineral waters.

—A. L. S.

VIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A.)—CHEMISTRY OF FOODS.

The Suitability of Flour for Baking. Zeit. Anal. Chem. 1891, 30, 509—510.

This property of flour being best investigated by baking a small sample, Kreusler has devised a process for its convenient manipulation. A dough is prepared by mixing 25 grms. of the flour, 12.5 of water, 0.6 of yeast, and 0.3 of common salt. This is introduced into a cylindrical "tin" about 60 mm. in diameter and the same height, the bottom and top of which are closed by smooth tinned plates. The lump of dough, which should fill from $\frac{1}{3}$ — $\frac{1}{2}$ of the tin, is rammed down with a small pestle and dried for two hours at 30°; it is then tied round with wire and introduced into an oil-bath heated to 250° for 20 minutes. The better or worse quality of the flour is judged by the greater or smaller volume of the baked mass, and to this end when cold it is introduced into a cylinder which is filled up to the top with small round glass beads. The beads are then poured off into a graduated measure, and the total contents of the cylinder being known, the volume of the marked sample is found by difference.—F. H. L.

The Calorific Value of the Constituents of Food and of their Derivatives. T. Stohmann and H. Langbein. J. Prakt. Chem. 1891, 44, 336—399.

This paper contains the results of a large number of experiments on the heat of combustion of food-stuffs, such as elastin, serum-albumen, haemoglobin, milk casein, yolk of egg, meat, peptone, &c., together with analyses of the bodies experimented with. Stohmann has previously carried out a similar series of experiments, employing his own modification of Frankland's potassium chlorate calorimeter (J. Prakt. Chem. 31, 273), whilst the determinations detailed in the present paper were carried out with a Berthelot's bomb (this Journal, 1886, 159). The values obtained by the latter method are all about 1.4 per cent. higher than those previously obtained, and the author regards the methods as equally accurate as far as the relative values are concerned. The paper concludes with determinations of the heat of combustion of derivatives of aliphatic substances, such as glycerol and its homologues, hippuric acid, urea, uric acid, asparagine, creatine, guanine, and caffeine. The results obtained agree well with those previously got by Berthelot and André (Ann. Chem. [6], 22, 5), except in the case of asparagine, in which case the authors' result is considerably higher. The heat of formation of several of these bodies in relation to that of their corresponding acids or homologues is also dwelt upon.—C. A. K.

Composition of Milk. L. Shishkoff. J. Russ. Chem. Soc. 1891, 23, 261. Preliminary Communication.

The author has succeeded in obtaining the fat of milk by the action of chloroform or carbon bisulphide in a peculiar active state in which it is capable of forming very easily an emulsion with the weakest solution of alkaline carbonate. This state being very inconstant, the fat loses it very soon. The author is inclined to regard such fat as an allotropic variety.

He further presumes that the close union of fat, albuminous substance, and mineral salts in milk is easily explained if we admit that a sort of dissociation is going on in the milk vesicles; the mineral acids of the salts combining with casein, sugar, and altered fat, act on the glycerol portion of the latter, whilst on the other hand the bases of the salts form separate compounds with albumen, which also act upon fat. This co-existence of acid and basic compounds in milk explains its peculiar reaction.

It is also asserted that the souring of milk is caused, not by the formation of lactic acid from sugar, but by

decomposition—under the influence of a ferment—of the compounds thus formed between the phosphoric and hydrochloric acids of salts in process of dissociation with casein and sugar, resulting in coagulation of the casein and formation of more acid compounds, which gradually neutralise the bases. Casein of milk is regarded by the author as merely a specific variety of albumen, and not as a special compound.—N. W. T.

PATENTS.

An Improvement in the Production of Butter and Apparatus therefor. T. T. Watson, Jabalpur, India. Eng. Pat. 15,121, September 24, 1890. 4d.

BUTTER is produced by blowing air through unskimmed milk, preferably at a temperature of 70°—80° F.—K. E. M.

An Improved Cooling or Refrigerating Vessel or Chamber for Use in the Manufacture of Cream, and the Preservation of Cream, Milk, Butter, Fish, and other Perishable Articles. G. W. Homer, Athelhampton Hall, and J. Hazel, Dorchester. Eng. Pat. 16,508, October 17, 1890. 8d.

THIS invention relates to a process of regulating the temperature of milk during the raising of the cream, and for protecting it and other perishable articles "from injury or contamination, dirt, insects, excessive cold, &c." A covered vessel holding the milk or other perishable article is placed in another vessel containing water (or ice); the cover is so constructed as to allow the water to entirely surround the inner vessel, whilst it admits a current of air, the temperature of which may be regulated.—E. S.

A Raw Extract of Meat Preparation. J. H. Niemann, Nagambie, Victoria. Eng. Pat. 17,774, November 5, 1890. 4d.

THE juice of raw lean beef or other meat is expressed mechanically in the cold, and mixed with pure cane-sugar in the proportion of 1 lb. of juice to 2 lb. of sugar. The mixture is stirred until the sugar is dissolved, and 15 drops of oil of lemon or other essential oil are then added for each pound of sugar used. This preparation can be completely manufactured in a day. It is said to be readily digestible and not subject to putrefactive fermentation. If fermentation should set in, it will be alcoholic in character, and consequently quite harmless.—H. T. P.

Improvements in the Preparation of Diastase for Use in the Manufacture of Bread and Biscuits, and for other Purposes. T. Fletcher, Birmingham. Eng. Pat. 20,803, December 20, 1890. 6d.

LOW dried (130° F.) malt, or a mixture of low dried malt and green or undried malt, is extracted with water at 120—135° F., with or without the addition of carbonate of soda in the proportion of 5—15 grms. per gallon of water, or of an equivalent quantity of carbonate of potash or carbonate of ammonia. The infusion thus obtained is evaporated to a solid or semi-liquid at a temperature not exceeding 120—135° F., preferably under reduced pressure. When evaporated to a specific gravity of 1.35—1.4, such an extract of diastase keeps well.—A. G. B.

Improvements in the Treatment of Cereals for Food and other Purposes, and in Apparatus therefor. A. J. Boulton, London. From J. J. Sheppard, Calais, France. Eng. Pat. 6417, April 15, 1891. 8d.

THE improvements claimed consist in "first cleaning the whole or untreated grain, steeping in or moistening with water, steaming to destroy the germs, and finally grinding and drying." The cleaning is done by any known process;

the steaming is done in a specially constructed cylindrical wire or other cage, revolving in a cylindrical kettle on axles, in one of which is a universal joint, and the other capable of being raised or lowered so that the cage may be inclined, to facilitate removal of the grain; the grinding is done in a specially constructed mill. For details the drawings in the original specification must be consulted.—A. G. B.

Improvements relating to the Preservation of Meat, and to Apparatus therefor. J. Falcinagne, Bordeaux, France. Eng. Pat. 14,521, August 27, 1891. 6d.

THE meat to be preserved is suspended from bars inside a closed cylindrical chamber, and is smoked by means of burning sulphur candles, lighted at their lower ends, which are suspended underneath a perforated false bottom placed just above the base of the apparatus. The false bottom is covered with wire gauze, on which is spread a layer of sodium carbonate or of lime; the fumes from the burning sulphur during their passage through this layer, form a sulphite, which spreads over the whole of the apparatus, and effectually preserves the meat. Drawings and details of the apparatus are given in the original specification.—H. T. P.

Improved Method of Preserving Eggs and other Articles of Food. V. C. H. Jessen, Copenhagen, Denmark. Eng. Pat. 15,580, September 14, 1891. 4d.

A SOLUTION of caoutchouc, rubber, or gutta-percha in a suitable solvent, such as naphtha or "benzine," is spread on one face of a tough, thin, and, preferably, transparent paper. Such paper is then wrapped closely round the egg or other article to be preserved, and so bent or twisted that the coated surfaces of the overlapping portions shall come together and adhere firmly, thus forming an air-proof and water-proof envelope for the egg. The egg is not in any way affected by coming in contact with the coating and does not crack when boiled, as is the case with eggs preserved by other methods. If thin and transparent paper be used the egg can be examined by means of a light for the purpose of ascertaining its condition.—A. G. B.

(B.)—SANITARY CHEMISTRY.

PATENTS.

Improvements in the Purification of Sewage and other Waste Liquors, and in the Recovery of Ammonia therefrom. W. E. Adeney, Dublin. Eng. Pat. 18,983, November 22, 1890. 4d.

THE sewage, &c., to be treated is "rendered neutral or but slightly alkaline by means of chalk or some mineral acid, as the case may require," and allowed to settle in a tank. The supernatant liquor is then mixed with 5 grains to the gallon of permanganate or manganate of soda or of potash, and run into a second tank. In 3–4 hours the whole of the manganese will have been deposited in the form of hydrated manganese dioxide, provided the amount of manganate or permanganate added was carefully regulated. Even a slight excess of these reagents renders the precipitation very incomplete. "The effluent may be discharged into a river or other watercourse without fear of after putrefaction being set up." The precipitated oxide is reconverted into manganate or permanganate in the usual way, and during the course of this operation the co-precipitated nitrogenous matters are recovered in the shape of ammonia.—H. T. P.

Improvements in and connected with the Cleansing of Filters and Filtering Material employed in the Filtration or Purification of Impure or Foul Liquids. C. H. Beloe and F. Candy, London. Eng. Pat. 19,220, November 26, 1890. 11d.

THIS patent relates more particularly to filters for purifying large quantities of water, such as are used in water-works. The special features of the invention are as follows:—
1. The sand of any one filter-bed may be readily cleansed by flushing through it from below the combined effluent water from several adjacent filters.

2. The dirt, scum, &c., collecting on the surface of the sand may be readily removed by swilling with large volumes of water supplied from a suitably-placed trough.

3. If it be required to thoroughly wash the sand, it is shovelled into a trough in which a rapid current of water is flowing. The mixture of sand and water is discharged into a box placed in the centre of the filter-bed; and the sand which settles in the box is afterwards replaced on the filter.—H. T. P.

Improvements relating to the Purification of Sewage and the Consumption of Town Refuse, and to the Utilisation of Sewage and Town Refuse for Obtaining Motive Power, and to Apparatus therefor. E. Christfield, Milton. Eng. Pat. 11,716, July 9, 1891. 1s. 1d.

By this invention all kinds of sewage and town refuse are said to be completely utilised: the liquid portion for the production of steam for motive purposes; the solid portion as fuel for evaporating and boiling down the sewage. The apparatus required is somewhat complicated and can only be properly understood by reference to the original specification.—H. T. P.

Method of Purifying Liquids, more particularly Sewage and Waste Water, and Apparatus appertaining thereto. A. Mylius, Berlin, Germany. Eng. Pat. 13,757, August 14, 1891. 6d.

TWO series of narrow troughs are arranged inside and near the top of a closed vessel. One series is maintained full of the sewage, &c., previously treated with milk of lime, whilst the other series contains dilute sulphuric acid. Cloths of some suitable material (asbestos in the case of the sulphuric acid) dip into each series of troughs, and, hanging over the sides, reach nearly to the bottom of the large containing vessel. The respective liquids gradually syphon over by capillary action through these cloths, and as a vacuum is maintained in the containing vessel, the ammonia contained in the sewage rapidly passes by evaporation to the sulphuric acid, forming ammonium sulphate. In practice, a number of these contrivances are placed in series, being so arranged that almost saturated acid and fresh sewage enter the first apparatus; whilst fresh acid and almost ammonia-free waste enter the last one.—H. T. P.

Method of Sterilising Liquids, particularly Sewage, and Apparatus appertaining thereto. A. Mylius, Berlin, Germany. Eng. Pat. 13,758, August 14, 1891. 6d.

THE object of this invention is to render innocuous micro-organisms still contained in liquids which have already been subjected to the ordinary purifying processes. The liquid to be treated is pumped into a closed tank, and from thence into a boiler where it is sterilised by heating. The hot water leaving the boiler is passed through "a ribbed pipe system," which is enclosed in the tank before mentioned for the purpose of heating fresh liquid and avoiding waste of heat. The sterilised liquid is finally disposed of in any suitable way.—H. T. P.

(C.)—DISINFECTANTS.

PATENTS.

An Improved Composition for Use as a Sanitary Reagent, Bleaching and Laundry Purposes, Coating Walls, and the like, Destroying Insects, and as a Substitute for Whiting. W. Corbould, London. Eng. Pat. 9189, June 1, 1891. 4d.

THE improved composition consists of a mixture of campher, whiting, and Jeyes' sanitary powder.—E. G. C.

A New Soluble Quinolene Derivative. A. Lembach and U. Schleicher, Biebrich, and C. J. Wolff, Wiesbaden, Germany. Eng. Pat. 13,693, August 14, 1891. 4d.

See under XX., page 1027.

XIX.—PAPER, PASTEBOARD, Etc.

PATENTS.

Improvements in the Manufacture of Decorative Material for Walls and other Decorative Purposes, and in the Machinery or Apparatus employed in the said Manufacture, the said Improvements being in part applicable to the Manufacture of Felt papers and Millboard. J. T. Palmer, Carshalton. Eng. Pat. 1227, September 3, 1893. (Second Edition.) 8d.

THE patent describes a method of manufacturing a decorative material for walls, &c., consisting essentially in the conveyance of the paper pulp used on to the wire cloth of a paper-making machine, a blanket or web capable of absorbing a great deal of moisture resting upon the sheet of paper pulp. The blanket travels with the pulp until it reaches the couch roll, where it leaves it and returns over rollers by which it is squeezed, and the water expressed from it being thus restored to a condition suitable for the absorption of a fresh quantity of water from the next portion of the sheet of paper pulp. The layer of paper material then passes on to a wire cloth, or a blanket, or both, and travels between pressure rollers, by which a pattern or design is impressed upon it, the back being left plain save for the print of the wire cloth upon it, which enables the finished product to adhere readily to surfaces to which it may be applied. The blankets used, including that upon which the sheet travels between the couch rolls and the first pressing rolls, are returned by means of a suitable set of rolls by which the moisture they have absorbed from the paper pulp is expressed. A brush roller scraper or cleaner may be used to free the blanket from adhering portions of pulp, and a tray may be provided to receive the expressed water and allow of its removal through a suitably arranged pipe. The paper material may be waterproofed, parchmentised, or impregnated with any desired substance during its passage through the machine described, or at any other suitable point in its manufacture, by ordinary well-known means. Variations in the details and arrangement of the process are also claimed.—E. J. B.

Improvements in the Manufacture of Cellulose. E. Misch, Vienna, Austria. Eng. Pat. 16,108, October 15, 1890. 6d.

THE process consists in steaming finely-divided wood, such as wood wool, for about three hours at a temperature of 100–120° C., whereby the resinous portion of the wood is dissolved, and the acidification of the soda-lye subsequently employed prevented. After steaming, the wood is treated at 150–160° C. with soda-lye varying in strength from 1 ounce to 1.5 lbs. sp. gr., the pressure being from 5 to 6 atmospheres. The mass, freed from excess of lye by means of a centrifugal machine, is then treated with chlorine gas. The soda-lye may be re-used until it becomes viscous, when it is evaporated and subjected to fractional distillation, whereby valuable neutral hydrocarbons are obtained, the residue being ignited in presence of air, and treated for recovery of caustic soda.—E. J. B.

Improvements in the Manufacture of Electrical Insulating Materials. J. R. Thaine, London. Eng. Pat. 16,747, October 21, 1890. 4d.

See under XI., page 1013.

An Improved Method of Actuating the Diaphragms of Strainers for Paper Pulp. H. J. Rogers, Watford. Eng. Pat. 19,376, November 28, 1890. 6d.

THE object of this invention is to reduce the number of working parts in a strainer, thereby saving original cost and reducing friction. The arrangement cannot be well understood without the drawings which accompany the specification.—E. J. B.

Improvements in Machines or Appliances used in the Manufacture of Paper. J. W. Bretherick, Darwen. Eng. Pat. 19,545, December 1, 1890. 6d.

THE inventor claims the use of brushes, the object of which is to keep clean the surface of the strainers used in the manufacture of paper.—E. J. B.

Improvements in Artificial Boards and the like. A. J. Boulton, London. From M. Hamilton, New York, U.S.A. Eng. Pat. 20,324, December 12, 1890. 4d.

ANY ordinary pulp, such as straw or Manilla, is mixed with silicate of soda, alum, bicarbonate of soda, ammonia, bicarbonate of potash, and starch, and made into rolls of paper. If desirable, a colour may be added. The sheets of paper are coated with glue and then united under pressure to form boards.—E. J. B.

Improvements in the Boiling Process for Producing Cellulose by Means of Sulphurous Acid. C. Kellner, Hallein, Austria. Eng. Pat. 12,970, July 31, 1891. 6d.

IN order to obviate the inconvenience caused by the precipitation of monosulphites in the boiler when solutions of bisulphites are heated with wood as in the ordinary method of preparing wood pulp, the inventor heats the solution of bisulphite in a separate vessel, from which it is run, hot, into the boiling vessel. The monosulphite is thus precipitated outside the boiler; it is afterwards re-dissolved by the sulphurous acid evolved during the boiling operation, thus forming part of a second charge of bisulphite.

—E. J. B.

An Improved Process and Apparatus for Preparing the Wood in the Manufacture of Wood Fibre. C. Kellner, Hallein, Austria. Eng. Pat. 12,971, July 31, 1891. 6d.

THE object of this invention is to remove the knots from wood from which it is intended to prepare pulp. This has hitherto been done by the costly operation of boring. According to the present process the wood, after been cut into small pieces, is passed between two plane, conical, or cylindrical surfaces, one of which revolves and the other is stationary. The revolving disc is furnished with a number of pins or teeth which cause the wood to be further subdivided into small leaflets. The knots which resist the action of the teeth can then be separated by means of a coarse sieve.—E. J. B.

An Improvement in the Treatment of Vegetable Fibre for Pulp Manufacture. J. D. Tompkins, Braintree, U.S.A. Eng. Pat. 14,032, August 19, 1891. 8d.

THE inventor claims the "treatment of fibrous materials for their conversion into pulp by suspending them in a constantly rising current of the treating liquids and subjecting them while thus suspended to the heating, cleansing, and chemical action of the suspending liquid." The effect is produced by causing a flow of liquid upwards through the bottom of the digester.—E. J. B.

Composition of Matter for Waterproofing Pulp and other Fibrous Articles. J. C. Chapman, London. From "The United Indurated Fibre Company," Portland, U.S.A. Eng. Pat. 14,272, August 24, 1891. 4d.

See under XIII., page 1017.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Sulphonic Derivatives of Camphor. E. Marsh and H. H. Cousins. J. Chem. Soc. (Trans.), 1891, 966—978.

THE substitution derivatives of camphor do not at present admit of systematic classification or prediction of the number of possible isomerides.

The sulphonic compounds have been found to rotate the planes of polarised light, a property hitherto observed in very few sulphur compounds and not at all in any sulphonic acid. Camphoric acid retains its optical activity unimpaired by the distillation of its anhydride through a red-hot tube, whereby a considerable part of it is decomposed. The recovered camphoric acid possesses, if anything, a still higher rotation now. Many of the sulphonic compounds are recrystallisable, and being also non-volatile, are difficult to purify. Some of the salts, however, crystallise well. The α - and β -chloro- and bromocamphors, α - and β -chloro- and bromo-camphor sulphonic acids, the α -chloro-sulphonic chloride, the α -bromo-camphor sulphonic chloride, and certain of the salts of the former were prepared.

The Existence of Hyoscyamine in Lettuce. T. S. Dymond. Proc. Chem. Soc. 1891, 165—166.

LETTUCE has been used in medicine from early times as a sedative, but the active constituent has never been with certainty determined. The author's attention was drawn a few months ago to the mydriatic action of an extract of lettuce used in medicine. It had been prepared from the flowering plant of common lettuce according to the direction of the *British Pharmacopœia*. An examination showed that the mydriatic action was due to an alkaloid. Commercial specimens of the extract of wild lettuce and of the variety of the edible plant known as cos lettuce, obtained from three different sources, together with a specimen of the dried flowering plant of wild lettuce, were all found to contain this alkaloid.

The alkaloid was most easily isolated by mixing the commercial extract with water acidified with acetic acid, adding alcohol till precipitation of nearly all the constituents of the extract occurred, filtering, evaporating the filtrate to a low bulk, filtering again, washing the filtrate with ether till free from fat, then rendering it alkaline and extracting the alkaloid with ether. The impure alkaloid thus obtained was purified by conversion into the oxalate, and the precipitation of this salt by ether from its alcoholic solution. On recovering the alkaloid and crystallising it from chloroform, it was obtained in silky needles having approximately the same melting point and other properties as hyoscyamine, the poisonous mydriatic alkaloid existing in belladonna, henbane, and other plants belonging to the natural order *Solanaceæ*.

The identity of the alkaloid with hyoscyamine was proved. The amount of hyoscyamine in the extract of common lettuce does not exceed 0.02 per cent., while in the flowering plant itself it cannot be more than 0.001 per cent. It appears that this is the first occasion on which hyoscyamine or any other alkaloid belonging to that mydriatic group has been found in a plant not a member of the natural order *Solanaceæ*, lettuce belonging to the natural order *Compositæ*.

Cryptopine. D. Rainy Brown and W. H. Perkin, jun. Proc. Chem. Soc. 1891, 166—167.

THE authors have commenced an investigation on the rare alkaloid cryptopine, which occurs in small quantity in opium, and which was first isolated by J. and H. Smith (Jahresbericht, 1867, 523), and subsequently analysed by Hesse (Annalen, Suppl. 3, 209).

Analyses of the base and of several of its salts led Hesse to assign to cryptopine the formula $C_{21}H_{23}NO_5$. The authors have prepared and analysed several samples which

had been purified by conversion into the oxalate and subsequent recrystallisation from isobutyl alcohol. The results accorded with Hesse's formula, as also those of the oxalate.

The oxalate, after repeated recrystallisation from water, was obtained in the form of beautiful glistening prisms.

On oxidation with potassium permanganate, cryptopine yields among other products a crystalline acid, $C_{10}H_{11}O_6$, melting point $179^\circ - 180^\circ$, which proves to be metahemipinic acid, $C_6H_5(CH_2O)_2(COOH)_2$ [1:2:4:5], the acid which Goldschmidt obtained from papaverine; this result is interesting in view of the fact that metahemipinic acid, up to the present time, has only been obtained from papaverine.

Cryptopine contains only two methoxy groups, as shown by its behaviour when treated with hydrogen iodide, these two groups being situated in that part of the molecule which is converted into metahemipinic acid on oxidation.

ψ -Tropine. C. Liebermann. Ber. 1891, 24, 2587.

ψ -TROFINE (Ber. 1891, 24, 2344) yields tropic acid on oxidation under similar conditions to the formation of the same acid from tropine, and as in the latter reaction some ecgoninic acid is formed simultaneously.—C. A. K.

Adonin: a Glucoside contained in Adonis Amurensis.

Y. Takara. Ber. 1891, 24, 2579—2582.

CERVELLO has given the name *Adonidin* to the active principle of *Adonis vernalis*, an amorphous glucoside, free from nitrogen, possessing a very bitter taste, and having a physiological action akin to, but more powerful than that of *digitalin*. The author has investigated the nature of the active principle of *Adonis amurensis*, a native in Japan, and which is valued as a decorative plant, and finds it to consist of an amorphous glucoside having the formula $C_{20}H_{31}O_{10}$. It forms a yellowish gum-like mass which yields a white powder when pulverised and is readily soluble in water and alcohol, almost insoluble in ether. The aqueous solution has a very bitter taste and becomes turbid on warming owing to the separation of the glucoside from the hot solution. This solution is precipitated by tannic acid, picric acid, gold chloride, &c., thus showing the presence of a glucoside. Concentrated nitric, sulphuric, and hydrochloric acids give indigo-blue, black red, and rose red colourations respectively. Mineral acids readily decompose the glucoside in aqueous solution, yielding 32 per cent. of sugar and 38.5 per cent. of a resinous body soluble in ether. The physiological action of the glucoside, for which the name of *Adonin* is proposed, is similar to that of Cervello's *Adonidin* except that it is physiologically very much less active, for which reason the author is of opinion that it may be successfully employed for therapeutic purposes. The yield of Adonin obtained was 1.94 per cent. on the dried roots from which it was extracted by means of 90 per cent. alcohol.—C. A. K.

The Hygroscopicity of Camphor and of Thymol.

G. Clautrian. Ber. 1891, 24, 2612—2614.

PHYSIOLOGICAL investigations on the sensitiveness of a ferment led Errara to the conclusion that camphor is decidedly hygroscopic whilst thymol is hardly so at all. The author has confirmed this by exposing Japan camphor and thymol in weighed quantities in a moist atmosphere and ascertaining the increase in weight, the results being checked by dehydrating the products obtained over strong sulphuric acid. Special care was taken during the experiments to avoid loss of material by sublimation. Full details in regard to these precautions are given. 10 grms. of camphor were found to absorb 0.022 grm. and 0.032 grm. of water respectively in two experiments, whilst thymol does not absorb appreciable quantities of moisture. The water absorbed by the camphor is so readily removed that the absorption can only be regarded as physical; camphor saturated with moisture will even part with some to a

second portion of camphor, less rich in moisture. The author remarks that in regarding the hygroscopic qualities of bodies, two quantities must be borne in mind, viz., both the extent and the intensity of the action. For instance, camphor is only slightly hygroscopic in respect to the quantity of moisture it can absorb, but it has nevertheless a great affinity for a certain amount of moisture.—C. A. K.

Studies on Artificial Musk. A. Baur. Ber. 1891, 24, 2832—2843.

The author has previously shown (Ber. 1883, 16, 2559) the essential resin contains two butyl-toluene nuclei, one a para and the other a meta-compound. The latter is obtained synthetically by the action of isobutyl-bromide on toluene in presence of aluminium chloride, and forms the starting point for the preparation of artificial musk which is manufactured by the "Société des produits Chimiques de Thann et de Mulhouse" as "*Musc Baur*" (this Journal, 1889, 1004; 1890, 545 and 965; 1891, 655 and 571). The present paper deals with further investigations on this meta-butyl-toluene and its derivatives. The product is obtained synthetically, not only by the action of isobutyl-bromide on toluene in presence of aluminium chloride, but also when tertiary-butyl chloride is employed, the bodies obtained in the two cases being in every respect identical. Hence the hydrocarbon is to be regarded as tertiary butyl-toluene and not as isobutyl-toluene, and in its formation from isobutyl iodide, a molecular rearrangement must take place as is frequently the case in Friedel and Crafts' reaction. The following formulae represent the constitution of iso-butyl and of tertiary-butyl-toluene—

By the action of fuming nitric acid butyl-toluene yields a mono- and a dinitro compound. The former is a yellow oil, boiling without decomposition, and possessing a peculiar somewhat unpleasant smell that does not resemble that of musk. The latter is a brown oil boiling at 224—225°, and both yield the trinitro-compound on further treatment with nitric acid. This trinitro-compound is the "artificial musk," and is best prepared by treating the hydrocarbon with a mixture of nitric and sulphuric acids. It melts at 96—97° C., and separates from alcohol in pale yellow needles which have an intense smell of musk. It is insoluble in water, readily soluble in alcohol and ether, and slightly volatile with steam. Of the possible formulae for the body, the author regards the following as the most probable:—

It forms a crystalline compound with naphthalene, melting at 89—90° C., and having the composition—

Aniline also combines with trinitro-butyl-toluene to form two crystalline compounds, $3\text{C}_{10}\text{H}_7 \cdot (\text{NO}_2)_3 + 2\text{C}_6\text{H}_5 \cdot \text{NH}_2$ and $\text{C}_{10}\text{H}_7 \cdot (\text{NO}_2)_3 \cdot \text{C}_6\text{H}_5 \cdot \text{NH}_2$, of which the latter is the more soluble. The *Mono-amido-compound* yields the corresponding *Mono-amido-compound* on reduction, $\text{C}_{10}\text{H}_7 \cdot \text{NH}_2$, which is identical with the body already obtained by Effront (Ber. 1884, 17, 2322) by the action of ortho-toluidine on iso-butyl alcohol. It is a colourless oil which turns brown in the air and boils at 245° C. *Mono-amido-dinitro butyl-toluene*, $\text{C}_{10}\text{H}_7 \cdot (\text{NO}_2)_2 \cdot \text{NH}_2$, is formed by the reduction of the trinitro compound by means of ammonium sulphide. This product separates from alcohol in yellow brown needles which melt at 125—126°. It is insoluble in water and forms a crystalline hydrochloride.

Homologues of artificial musk result by replacing the toluene by its homologues and nitrating the resulting hydrocarbons. In this way the trinitro compounds of butyl-meta-xylene and of butyl-ethyl benzene have been prepared. They both possess a smell of musk, but as substitutes for the natural product are inferior to the trinitro-butyl-toluene.

In the preparation of the butyl-toluene for making artificial musk a number of hydrocarbons other than tertiary-butyl-toluene result from which the latter should be isolated by careful fractionation. Also the butyl bromide employed should be prepared from butyl alcohol that is free from amyl alcohol, otherwise amyl-toluenes result which when converted into their trinitro compounds deteriorate both the odour and the crystallising power of the "artificial musk." The investigations are being continued.—C. A. K.

Paeonol. W. N. Nagai. Ber. 1891, 15, 2847—2853.

This substance occurs in the root of the bark of *Paeonia Montan.* According to the author the best way of obtaining it is as follows:—The finely-powdered bark is exhausted with ether, and after recovering part of this by distillation the concentrated solution is shaken with solution of sodium carbonate which removes some impurities but does not dissolve the paeonol. This may, however, be removed by agitation with sodium hydroxide, from which solution it may then again be separated by the addition of sulphuric acid and agitation with ether. After evaporating the ether an oily substance is left which, however, gradually solidifies to a crystalline mass. The compound may be purified by recrystallisation from alcohol.

Properties.—It crystallises in colourless glittering needles which fuse at 50° C. It volatilises in a current of steam, has an aromatic odour, a burning taste, is sparingly soluble in cold, more so in hot water, and freely soluble in alcohol, ether, benzene, chloroform, and carbon disulphide. Ferrie chloride gives a reddish-violet colour, when added to its aqueous or alcoholic solution. Strong sulphuric acid dissolves the substance without change of colour. The compound acts as a weak acid, being dissolved by the caustic alkalis, but not by their carbonates or even by ammonia.

Its formula, according to the author, is $\text{C}_9\text{H}_{10}\text{O}_3$.

Derivates.—When fused in a silver dish with four parts of potassium hydroxide and a little water it turns red, finally brown. If the mass is dissolved in water and acidified with sulphuric acid, white crystalline needles are obtained, which after recrystallisation from hot water, prove to be Nencki's and Sieber's resacetophenone (dioxycetophenone)—

If after this substance has separated, the mother-liquor is shaken out with ether a substance is obtained which after purification with sodium hydroxide and re-extraction with ether proves to be α -resorcylic acid $\text{C}_6\text{H}_3\text{CO}_2\text{H} \cdot (\text{OH}) \cdot (\text{OH})$.

Resorcinol, $\text{C}_6\text{H}_3(\text{OH}) \cdot (\text{OH})$, is also formed in small quantity.

Action of hydriodic acid. By heating paeonol for five hours in a sealed tube at 150° C., it is quantitatively decomposed into methyl iodide and resacetophenone.

According to the author's views, Paeonol is a methoxylated, hydroxylated acetophenone, or rather a methylated resacetophenone. Although a phenol-ketone, it does not combine with sodium-hydrogen sulphate, and in this respect it behaves like acetophenone.—L. de K.

The Behaviour of Azoimide with Living Organisms.

O. Loew. Ber. 1891, 15, 2947—2953.

AZOIMIDE ($\text{N}_2 \cdot \text{NH}$) seems to have a great future as a probable strong disinfectant, antiseptic, or germ destroyer. This fact the experiments described with various lower vegetable and animal organisms fully proves. The substance is, however, an active poison, and so could not be used to preserve articles of food.—L. de K.

Some of the Constituents of Paracoto Bark. G. Ciamician and P. Silber. Ber. 1891, 24, 2977--2990.

In a previous communication (this Journal, 1891, 383) on "Hydrocotéine" the authors regarded that body as a derivative of benzo-phenone, of the formula--

They are, however, as yet unable to positively confirm that formula, owing to the indefinite nature of the products obtained by the action of most reagents on hydrocotéine. Nor did the authors succeed in preparing its oxime or hydrazone. Phosphorus pentachloride acts readily on hydrocotéine. The resulting product contains benzoyl chloride, benzyltrichloride, a new body of the formula, $C_6H_5Cl_2O_2$, and a considerable amount of resinous matter. The new compound is volatile with great difficulty in steam, and crystallises from alcohol in long colourless needles, melting at $174^\circ C$. Assuming the authors' formula for hydrocotéine to be correct, the new substance is probably the dimethyl ether of a trichlorophenol, $C_6HCl_3(OCH_3)_2$. Methyl hydrocotéine, when treated with phosphorus pentachloride, yields the corresponding trimethyl ether, $C_6Cl_3(OCH_3)_3$, which forms fine white needles, melting at 130° — $131^\circ C$. Besides this substance a small quantity of dichloromethylhydrocotéine, $C_6H_5.CO.C_6H_4Cl_2(OCH_3)_2$, is produced. It crystallises in colourless prisms, melting at 81° — $82^\circ C$.

Protocotéine is the name the authors give to a body occurring in crude hydrocotéine. It may be separated from the latter by repeated fractional crystallisation from alcohol in which it is less soluble than hydrocotéine.

Protocotéine, $C_{16}H_{14}O_6$.—Pale yellowish monoclinic prisms melting at 141° — $142^\circ C$. It is soluble in alcohol, ether, glacial acetic acid, benzene, and chloroform; insoluble in water. A solution of protocotéine in weak alcohol is coloured reddish-brown by ferric chloride. With nitric acid ($1:4$) it gives in the cold a blue-green colour, which on warming changes to a dirty reddish-brown tint. Protocotéine dissolves in alkalis, forming a yellow solution from which it is reprecipitated by carbonic acid. It contains two methoxy groups, like hydrocotéine.

Mono-acetylprotocotéine, $C_{14}H_{12}O_5(OCH_3)_2(C_2H_3O_2)$, forms colourless crystals melting at $103^\circ C$. It is insoluble in water, soluble in ether, hot alcohol, chloroform, and acetic ether.

Methyl-protocotéine crystallises in colourless prisms, which melt at 134° — $135^\circ C$. It is insoluble in water and alkalis.

The presence of the group CO in protocotéine is proved by the fact that it readily forms a phenylhydrazone. It separates from water in small colourless prisms, melting at $211^\circ C$.

Dibromprotocotéine, $C_{16}H_{12}Br_2O_6$, crystallises in silky scales, which melt at $170^\circ C$. It is soluble in ether, alcohol, glacial acetic acid, and insoluble in water.

Acetyl bromprotocotéine, $C_{16}H_{12}BrO_5(C_2H_3O_2)$, is obtained in fine white needles. It melts at $175^\circ C$, and is insoluble in water and alkalis.

By fusion with potash, or heating with hydrochloric acid to $140^\circ C$, protocotéine yields protocatechuic acid, hence the name "protocatechine." Under the same circumstances hydrocotéine gives benzoic acid. Protocotéine and methyl-protocotéine on treatment with phosphorus pentachloride yield, amongst other products, two bodies, melting respectively at $174^\circ C$ and 130° — $131^\circ C$, which are identical with those similarly obtained from hydrocotéine and methyl-hydrocotéine. These results agree with the assumption that protocotéine differs from hydrocotéine in the manner exemplified in the following formula:—

Hydrocotéine, or, as the authors now prefer to call it, *Benzocotéine*,

Protocotéine.

Alkaline potassium permanganate converts protocotéine into an acid, which has not been further examined; and a neutral volatile body identical with *paracumarhydrin*, which was first obtained by Jobst and Hesse (Annalen, 199, 17) from paracotéine by boiling with potash.

It forms a hydrazone $C_{16}H_{14}O_5(N.HC_6H_5)$ crystallising in scales which melt at $114^\circ C$.—H. T. P.

Investigations on the Terpenes and their Derivatives. J. W. Brühl. Ber. 1891, 24, 3374—3416. (Third Communication.)

Part I.

The Camphors.—Research assisted by H. Biltz and A. Cantzler.—The author will investigate the constitution and chemical and physical properties of the camphor and allied bodies, and proposes dividing his experiments into two classes. In this paper he deals with the chemical series of research alone, devoting himself to the camphor bodies, ether, and acid derivatives; also a few salts.

Menthol, $C_{10}H_{20}O$.—This substance behaves as a derivative of hexahydrocymene, and as a secondary alcohol of this aromatic body. Among other results, he finds menthol gives no addition products with hydrogen, halogen, or halogen acids. It has also been proved that menthol can be oxidised by dry methods into cymene. For this purpose anhydrous copper sulphate was used, heated under pressure in tubes to 250 — 280° . The oil produced was dried and distilled over nitrogen, and fractionated. It proved to be cymene.

By this result it is shown that menthol may be easily converted into cymene by certain oxidising agents, the reaction following the equation—

Menthylethylether, $C_{10}H_{20}O.C_2H_5$.—The author refers to the preparation of this body. 30 grms. of anhydrous toluene were dissolved in 30 grms. of menthol, 8 grms. of sodium added, and the whole heated to the boiling point in an oil-bath. The product was treated with ethyl-iodide, and heated till alkalinity was destroyed. The sodium iodide was dissolved out by water, the unaltered toluene and ethyl-iodide distilled off. The product was heated with sodium, and distilled over sodium in an atmosphere of nitrogen. A substance was thus obtained as a colourless mobile liquid with a slight odour of menthol, and is the ether sought. It boiled at 211.5° — 212° .

(2.) *Borneol*, $C_{10}H_{16}O$.—Consists of common or Japan camphor with the addition of two hydrogen atoms. The camphor being a ketone, the constitution of borneol answers to the corresponding secondary alcohol. The author discusses the preparation of borneol obtained from various sources, arriving at the conclusion that the purest and cleanest product is to be obtained from borneol-carboxylic acid. Its melting point is 206° — $207^\circ C$. The product obtained from crude borneol and Baubigny's method, and two distillations with steam, is a crystalline white product, which after pressing and drying melts at 202° to 203° .

Bornylethylether, $C_{10}H_{16}O.C_2H_5$.—As solvent for the preparation of this compound from borneol, xylene was used, the action with sodium not taking place till after the metal had fused. The preparation was carried on in a manner similar to the production of the menthyl ether already described. This ether is a colourless, viscous, and dense liquid, with a very mild odour. It boils at 204° — 204.5° .

Bornylmethylether ($C_{10}H_{16}O_2$). CH_3 .—Prepared by methods similar to those by which the previously described ethers were formed. It yields a crystalline mass of fine white, rhombic prisms, melting at 167° — 168° . In the fused state it shows a beautiful bluish-yellow fluorescence.

Bornylmethylether, $C_{10}H_{16}O.C_2H_5$.—This derivative was also prepared.

(3.) *Action of Sodium on Camphor.*—This reaction carried on in a neutral solution yields besides sodium-camphor also sodium-borneol: for as the formation of the

first-named body proceeds, the hydrogen set free reduces a further portion of camphor.

Ethyl Camphor.—This is prepared by Baubigny's method by means of ethyl-iodide on camphor. By distillation in vacuo and many fractionations, a colourless liquid boiling at 131—136° was obtained.

Camphocarboxylic Acid and Derivatives.—This acid was prepared by Baubigny's method (*Ann. Chem. Phys.* (4), 19, 221, 1870), the reaction proceeding as follows:—

The author deals in extenso with the various probable formula, and action of sodium and CO_2 on camphor, and further the action on these derivatives of water.

Salts and ethers of camphocarboxylic acid were prepared by the author.

Sodium Salt.—Crystalline powder, slightly soluble in water, alcohol, methyl alcohol, and chloroform, insoluble in acetone, ether, and carbon bisulphide.

The Calcium Salt is with difficulty soluble in water and alcohol, and crystallises in needles.

The Potassium, Lithium, and Ammonium Salts were also prepared.

Camphocarboxylic ethylether, $C_{10}H_{18}O_2$, is a colourless liquid of powerful odour, and of the consistency of glycerol.

As a result of the action of phenylhydrazine on camphocarboxylic acid a snow-white crystalline powder is obtained, melting at 131—132°, and having the formula—

It is very easily soluble in benzene and chloroform, less so in ether and alcohol. This body has been called *Camphopropazobone*, and has been provisionally patented.

On a variety of theoretical grounds the author believes the constitution formula of camphor to be most correctly represented by—

—E. F. H.

A New Method for the Preparation of Phenoldicarboxylic Acids. H. Hilde. *J. Prakt. Chem.* 1891, 44, 5—14.

OST has shown that Kolbe's method for the preparation of hydroxy-carboxylic acids of the aromatic series applies also to the production of hydroxydicarboxylic acids, and he has prepared both hydroxy-isophthalic acid and hydroxy-terephthalic acid by the action of carbon dioxide on basic sodium salicylate at 200—400°C. (*J. Prakt. Chem.* 14, 93, and 15, 361). The acids that result in this way are unsymmetrical and no adjacent hydroxydicarboxylic acids could be obtained thus. The author finds, however, that if the sodium salt of the methyl ester of salicylic acid be treated with carbon dioxide under increased pressure, on the lines of Schmitt's method for the preparation of salicylic acid (this Journal, 1885, 688) adjacent hydroxydicarboxylic acids result, and in this way such acids derived from ortho-, meta- and parahydroxy-benzene acid have been prepared. The sodium salt of gambiric acid, when heated with an excess of carbon dioxide in an autoclave for about 24 hours to 150° yields the methyl ester of the adjacent hydroxyththalic acid, $C_8H_7CO_2OH.H_2CO_2(COOH) + 2H_2O$. The ethylester of salicylic acid behaves similarly when

treated with carbon dioxide under pressure, but the phenyl ester (salol) does not react. The diphenyl ester of the adjacent isophthalic acid results by treating the acid with phenol and phosphorus oxychloride at 170°—180°. It crystallises from alcohol in colourless prisms melting at 99°C., and differs from salol in forming a fairly stable sodium salt, $C_{16}H_{13}O_4Na(CO_2OC_6H_5)_2$. The sodium salts of the ethyl esters of both meta- and para-hydroxybenzoic acid react readily with carbon dioxide at 170°C. to form the methyl esters of the adjacent hydroxy-carboxylic acids. The free acids have the formulæ—

Hydroxy-terephthalic acid.

Hydroxy-isophthalic acid.

The ethyl ester of the latter forms monoclinic plates which melt at 191—195°C. The sodium salt of the ester crystallises with 4 molecules of water; the silver salt is soluble in hot water. The phenyl ester—

crystallises in colourless needles which melt at 64°—65°C. and readily forms a sodium salt. The free acid and the hydroxy-terephthalic have been previously prepared by other means. The methods are patented—C. A. K.

PATENTS.

A New Soluble Quinoline Derivative. A. Lembach and F. Schleicher, Biebrich, and C. J. Wolff, Wiesbaden, Germany. Eng. Pat. 13,693, August 14, 1891. 4d.

THE object of the invention is to prepare a soluble quinoline derivative to be used for antiseptic and other purposes. The derivative prepared is quinolinequinophenol sulphate, which may be obtained either by treating orthohydroxyquinoline sulphate with quinoline, or by treating quinoline sulphate with orthohydroxyquinoline. The mixtures are boiled with water until the product is insoluble in ether. The compound formed consists of a yellow solid resembling fused ferric chloride in appearance, and like this body it is very hygroscopic. The quantities required for the preparation are given.—C. A. K.

A Process for the Preparation of Phenylestersalicylic Acid or Salol from Salicylic Acid. Paul Ernert, Ludwigshafen, Germany. Eng. Pat. 14,224, August 22, 1891. 4d.

IT is generally stated that salicylic acid sublimes undecomposed when carefully heated, but that it is partially decomposed when rapidly distilled into carbonic acid and phenol. The author has found that the extent of the decomposition depends upon the temperature, and that at a high temperature the acid separates water and carbon dioxide with the formation of salol if the water formed during the heating be distilled off and the access of air carefully avoided. To prepare salol by this means pure or crude salicylic acid is heated in a flask to 220°—230°C. The flask is provided with a narrow neck which projects so far out of the bath that the steam evolved in the reaction does not condense and run back into the flask

but passes on to a small bulb connected with the neck. The flask is filled with carbonic acid before heating and a gentle current of the gas passes through in the opposite direction to the issuing vapours, during the operation. The resulting salol is washed with water or, if necessary, with soda and purified by recrystallisation from alcohol or other suitable solvent.

The author is of opinion that the formation of the salol most probably takes place with the intermediate formation of an anhydride of salicylic acid according to the following equations:—

This idea is favoured by the fact that the addition of phenol does not increase the yield of salol, which amounts to the theoretical quantity, 2 kilos. of salicylic acid giving 1.4--1.5 kilos. of salol.—C. A. K.

Production of a Novel Pyrazolon. O. Imray, London. From the "Farbwerke vormals Meister, Lucius und Brüning," Hoechst-on-the-Maine, Germany. Eng. Pat. 18,024, November 8, 1890. 4d

KNOWN has shown that pyrazol derivatives result by the action of phenylhydrazine on unsaturated ketones and also that a pyrazolone derivative is formed by the action of phenylhydrazine on cinnamic acid (Ber. 1887, 20, 1107). The new derivative is obtained by the action of phenylhydrazine on crotonic acid at 130°—150° C., when a yellow-red melt results, which is extracted with methyl alcohol. When purified by recrystallisation from methyl alcohol it forms white crystals melting at 84°—85° C. It is only sparingly soluble in hot water, and when treated with oxidising agents, such as ferric chloride, it gives a flocculent blue precipitate, soluble in chloroform, with an intense blue colour—a general reaction for the pyrazolones.—C. A. K.

Production of Sodium-formylphenylhydrazine, and of Symmetric Alkylphenylhydrazine and of Analogous Compounds. O. Imray, London. From the "Farbwerke vormals Meister, Lucius und Brüning," Hoechst-on-the-Maine, Germany. Eng. Pat. 18,025, November 8, 1890. 6d.

In order to prepare secondary phenylhydrazines, phenylhydrazine has been treated with sodium and the sodium compound acted upon by alkyl haloids. In this way it is only the hydrogen of the imido group in the hydrazine that is thus replaced and the resulting compounds are the unsymmetrical alkyl phenylhydrazines, the methyl compound, for instance, having the formula $\text{C}_6\text{H}_5 \cdot \text{N} \cdot (\text{CH}_3) \cdot \text{NH}_2$. If, however, formyl phenylhydrazine, obtained by boiling phenylhydrazine with formic acid, be boiled in xylene solution with sodium and the solution then treated with an alkyl iodide a symmetric alkyl phenylhydrazine results according to the equation—

The sodium compound is very explosive when dry, and cannot therefore be isolated, so that, in order to prepare the

alkylhydrazine, the above xylene solution of the sodium compound is treated direct with the alkyl haloid. When the reaction is completed the solution is filtered, the xylene distilled off, and the formyl compound left behind saponified by means of alkali or of acid. The alkylphenylhydrazine is then extracted with ether and finally distilled in vacuo. The methyl compound is a yellowish oil boiling at 220°—230° C. When oxidised with mercuric oxide "azophenyl-methyl" results. The ethyl compound is similarly prepared and is identical with that got by other means.—C. A. K.

Improvements in the Manufacture and Production of Medicinal Compounds from Etheral Oils. J. Y. Johnson, London. From F. von Heyden (Nachfolger), Radebeul, Germany. Eng. Pat. 19,074, November 24, 1890. 6d.

The medicinal application of the odoriferous constituents of the etheral oils, such as menthol, borneol, geraniol, thymol, carvacrol, eugenol, and gaultheria oil which possess peculiar physiological and antiseptic properties, has been greatly restricted, owing to their strong taste and smell and their corrosive action on the mucous membrane. The patentee prepares odourless, tasteless, neutral products from these hydroxy compounds, or from the oils containing them, by converting them into carbonates, carbamates, or alkyl-carbonates, which products are without action on the mucous membrane. The carbonates are produced either by the action of one molecule of carbonyl chloride in benzene solution on two molecules of the hydroxy compound at 150° in a vessel capable of withstanding pressure, or by treating two molecules of the latter dissolved in caustic soda with phosgene gas. The following equations represent the changes that occur:—

The carbamates are prepared by substituting phosgene amide for phosgene—

in the above reactions or by treating the etheral oil first with carbonyl chloride and subsequently with ammonia.

These carbonates and carbamates are, with the exception of carvacrol carbonate, crystalline bodies. The menthol carbonate has the composition $\text{CO}(\text{O} \cdot \text{C}_{10}\text{H}_{19})_2$, and melts at 160° C; the carbamate—

melts at 161° C. The melting points of the corresponding compounds of dextro- and levo-borneol, gnaiaicol, creosol, eugenol, carvacrol, thymol, and gaultheria oil are given, together with details of typical methods of preparation. Ethyl salicylate, iso-eugenol, and also creosote can be converted into similar derivatives, the last yielding a mixture of carbonates or carbamates of phenols. Alkyl carbonates can be similarly obtained, such as eugenol methyl carbonate—

which results by the action of chloroformic ester on eugenol or its sodium compound. Several methyl and ethyl compounds of the various etheral oils have been thus prepared, all of which are liquids (except ethyl eugenol carbonate, melting point 26°—27°) and are on this account specially suitable for injections.

These preparations are split up into carbonic acid or ammonia and the active hydroxyl compound in the system.

—C. A. K.

Manufacture of a Compound of Antipyrine and Iodine. O. Inray, London. From the "Farbwerke vormals Meister, Lucius, und Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 19,576, December 1, 1890. 4d.

Two parts by weight of antipyrine are dissolved in 20 parts by weight of water, and the solution heated to boiling. Three parts by weight of potassium carbonate and 2.8 parts by weight of iodine are alternately added in small quantities at a time to the solution. A yellow-brown powder separates after the completion of the reaction which is washed with water and crystallised from dilute alcohol. When pure the product forms white prismatic needles melting at 158—160° C. It is nearly insoluble in water, but readily soluble in hot alcohol. "For the potassium carbonate soda or free alkali or an alkaline earth may be substituted."—C. A. K.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

An Improved Apparatus for keeping Disks containing Liquids in Regular Motion, specially for Use in the Practice of Photography. J. W. Hunter, London. Eng. Pat. 18,734, November 19, 1890. 8d.

A LEVEL table or platform, on which the disk is placed, is fixed to a vertical stem capable of oscillating on its own axis. The motion is imparted to the stem by a fork actuated by a running-down motion controlled by a fan or heavy wheel.—C. H. B.

Improved Apparatus for Use in Photographic Printing. L. J. Sellar, Corunna, Spain. Eng. Pat. 18,967, November 22, 1890. 8d.

FRAMES containing prints to be vignettied, cracked negatives, &c. are placed on small level platforms or supports, attached to vertical stems that are caused to rotate slowly by means of any convenient motive power.—C. H. B.

Improvements in Photographic Dishes. E. S. Norcombe, Birmingham. Eng. Pat. 19,358, November 28, 1890. 6d.

THE dishes are made of transparent glass and have, near the bottom and parallel with it, on two or more sides, a deep groove, into which the plate slips and is thus prevented from falling out when the dish is inclined. A similar result is obtained by means of a row of projections or nipples. The developer or other solution can thus be poured out of the dish and the plate examined by holding the bottom of the dish near the light. When films are used an open glass frame with an outer flange on the lower edge, is placed on the top of the film as it lies in one of the dishes just described, and the flange slips into the groove or under the nipples and keeps the film in its place.—C. H. B.

Improvements in the Means for Washing Photographic Negatives and Prints. A. Palmer, Nottingham. Eng. Pat. 20,199, December 11, 1890. 8d.

A LONG trough is used with sliding adjustable racks capable of supporting negatives in either a vertical or horizontal position. When the trough is used for prints the racks are removed. The water enters at one of the bottom corners by means of a pipe running along the whole length of the bottom and terminating at the other end in a funnel somewhat above the level of the tank. The waste water escapes at the top through an overflow pipe at the corner, diagonally opposite to that at which the water enters.

—C. H. B.

Improvements in and relating to Photochromographs. L. Meyer, Berlin, Germany. Eng. Pat. 14,943, September 4, 1891. 4d.

A PHOTOLITHOGRAPH is illuminated with oil colours, the outlines and chiaroscuro being produced by the lithograph. When thoroughly dry the print is transferred to artists' canvas or other suitable foundation and the paper is stripped off. There is then on the canvas a coloured picture, with the shading of the photolithograph on its surface.—C. H. B.

A New or Improved Process for Producing Photographic Pictures having Colours resembling those of the Objects from which they are obtained. V. Mathieu, London. Eng. Pat. 16,091, September 22, 1891. 4d.

AN ordinary photographic print, preferably of a black colour, is made transparent by repeated treatment with a mixture of alcohol and Venice turpentine, followed by baking in a hot-air oven, and oil colours are applied to the back of the transparent print.—C. H. B.

On the Explosive Properties of Trinitrotoluene. C. Häusermann. Zeits. f. angew. Chem. 1891, 508—511.

THE author has made various experiments to test the safety and suitability of trinitrotoluene as an explosive, and states that there are no difficulties or dangers in its manufacture which could hinder it from entering the field with other explosives. In order to test its stability when kept for some time he exposed portions of this body in the air for several months to varying temperatures (-10° — $+50^{\circ}$), and found that when the trinitrotoluene had been crystallised from alcohol only a slight surface yellow colour was noticed, and no change could be detected in any of its other properties, but when the body had only been freed from acid by washing with water and dilute soda and allowed to stand a short time, traces of acid vapours were frequently detected by the "heat test." Some of the trinitrotoluene was rubbed in an iron mortar, alone and mixed with sand, and no change was observed. On striking it on an anvil, only a very slight decomposition accompanied by evolution of smoke took place. On being wrapped in tin-foil and struck on the anvil, only the slightest decomposition could be detected, and this did not give rise to a report or any appearance of fire. Further experiments showed that trinitrotoluene could not be exploded by flame or by heating in an open vessel in the air. Heated on platinum foil it first melts, then evaporates and catches fire, burning quietly with a very sooty flame. Projected on to a red-hot iron plate it simply burns rapidly. When heated in a test-tube it boils at 300°, and if the heat be continued it froths up and catches fire, leaving a large porous carbonaceous residue. Only when a large mass is rapidly heated in a covered vessel does feeble detonation take place, and this produces very slight effects. Seventy grams. of the powdered substance were placed in a closed cubical zinc case, the sides of which measured 4 cm. This case was placed on a cast-iron plate 2 cm. in thickness, and was fired by a fulminate detonator 35 mm. in length. The explosion was accompanied by a loud report, and a distinct, although faint, cloud of smoke. The iron plate was quite destroyed, and pieces of it scattered widely. Further experiments showed that it belongs to the class of shattering explosives. A mixture was also made of 1 part of trinitrotoluene and $3\frac{1}{2}$ parts of ammonium nitrate. Comparative experiments showed that

this mixture did less mechanical work on explosion than the trinitrotoluene alone, but more than a corresponding mixture of dinitrobenzene and ammonium nitrate. It is pointed out that the manufacture of an explosive by mixing trinitrotoluene and ammonium nitrate does not give rise to injurious fumes, as in the case of dinitrobenzene.—W. M.

PATENTS.

Improvements in Cartridge Cases. J. C. Butterfield and T. C. Batchelor, London. Eng. Pat. 19,659, December 2, 1890. 8d.

This invention consists in making metallic cartridge cases in two parts or shells, which after being filled with the explosive are united in the centre and screwed together or closed in any suitable manner.—W. M.

A Novel Explosive Compound. W. C. Gedge, London. From "The California Explosive Company," San Francisco, California. Eng. Pat. 11,326, July 3, 1891. 4d.

This is a mixture of methyl and ethyl nitrates, nitrobenzene, methyl alcohol, pyroxyline, and nitroglycerin which has been specially purified by treatment with ethyl alcohol.—W. M.

A Centrifugal Machine for Separating Acid from Nitrocellulose or for other like Purposes. R. Kron, Gollern, Germany. Eng. Pat. 13,612, August 12, 1891. 6d.

The centrifugal machine is provided with a perforated vessel or basket adapted to be tipped, in combination with a surrounding cylinder or guard which can be raised clear of the basket when the latter is being tipped.—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Chemical Manipulation. H. N. Warren. Chem. Zeit. 1891, 64, 146—147.

An efficient platinum crucible is prepared by folding a circular piece of platinum foil twice like a filter-paper. To make gold and silver crucibles a porcelain crucible is first covered externally with an ethereal solution of pyroxylin, when the ether has volatilised, a solution of gold chloride or silver nitrate is applied to dry pyroxylin, and while still moist is exposed to sulphurous acid fumes. The metallic coating thus produced can be increased electrically to any desired thickness by the use of the ordinary solutions. In this way a compact metallic crucible is obtained, which may be detached from the porcelain crucible by heating, and so destroying the intervening film of pyroxylin.

A good surface for coating with copper is a deposit of metallic antimony, obtained by exposing the flask or other cold objects to a flame of hydrogen antimonide.—D. A. L.

The Gravivolumeter, an Instrument by Means of which the Observed Volume of a Single Gas gives directly the Weight of the Gas. F. R. Japp. J. Chem. Soc. Trans. 1891, 894—903.

This apparatus is so constructed that, with an ordinary graduation in cubic centimetres, any desired single gas may, without observation of temperature or pressure, and without calculation, be measured under such conditions that each cubic centimetre represents a milligramme of the gas. The form of the apparatus is, with slight modifications, that of Lunge's gas volumeter (this Journal, 1890,

547); the method of employing the regulator is, however, different.

The apparatus, which is represented in the annexed drawing, consists of two gas burettes, of 50 cc. capacity

each, both furnished with obliquely bored taps. One of these burettes, A, which has a three-way tap, is the gas-measuring tube; the other, B, which need only have a single tap, performs the function of the regulator in Lunge's gas volumeter, and is termed the "regulator tube." As in Lunge's instrument, both tubes are moistened internally with a drop of water, in order that the gases they contain may be saturated with aqueous vapour, and both are connected by means of stout flexible tubing and a T-piece, with the same moveable reservoir of mercury, C. And since, in certain determinations, the level of the mercury reservoir is considerably below the lower end of the two burettes, and an inward leakage of air might thus occur at the junctions of the burettes with the india-rubber tubing, these junctions are surrounded with wider pieces of india-rubber tubing, D D, tied round the bottom and open at the top, and filled with water, so as to form a water-joint.

The 25 cc. division of the regulator tube is taken as the starting point in calculating what the author terms the "gravivolumetric values" of the different gases to be measured. Thus, in the case of nitrogen, he calculates to what volume 25 cc. of "standard-dry" nitrogen must be brought in order that 1 cc. would correspond with 1 mgrm. of the gas; that is to say, 25 cc. of standard-dry nitrogen weigh $0.001256 \times 25 = 0.0314$ grm.; and, therefore, these 31.4 mgrms. of nitrogen must be brought to the volume of 31.4 cc. The division 31.4 on the regulator tube is marked N_2 . Corresponding points are in like manner determined for the various other gases which it is desired to measure, and these points are similarly marked O_2 , CO_2 , &c., as the case may be, on the regulator tube. Finally, the thermometer and barometer are read (a process which is only necessary once for all in setting the regulator); the volume which 25 cc. of standard-dry air would occupy if measured moist at the observed temperature and pressure is calculated; and this calculated volume of air is admitted into the regulator tube and the tap closed. The instrument is now ready for use.

Suppose it is desired to ascertain the weight of a quantity of nitrogen contained in the measuring tube. The mercury

reservoir is lowered until the mercury in the regulator tube stands at the nitrogen mark, 31.4, at the same time adjusting the regulator tube itself, by raising or lowering it bodily, so that the mercury level in the measuring tube and the regulator tube may be the same. Under these circumstances each cubic centimetre of gas in the measuring tube represents a milligramme of nitrogen. For, since in the regulator tube 25 cc. of standard-dry air have been made to occupy the volume of 31.4 cc., and as the gases in the two tubes are under the same conditions as regards temperature, pressure, and saturation with aqueous vapour, therefore, in the measuring tube, every 25 cc. of standard-dry nitrogen has also been made to occupy the volume of 31.4 cc. But 25 cc. of standard-dry nitrogen weigh, as just stated, 31.4 mgrms.; so that the problem is solved, and the cubic centimetres and tenths of cubic centimetres give directly the weight of the gas in milligrammes and tenths of milligrammes.

The various other single (*i.e.*, unmixed) gases may be weighed in like manner by bringing the mercury in the regulator tube to the "gravimetric mark" of the gas in question, and adjusting the levels as before. An exception would be made in the case of hydrogen, which would be brought to such a volume that each cubic centimetre would contain a *tenth* of a milligramme.

Mixtures of gases may also be weighed, provided that the density of the mixture is known. Thus, in the case of air, the gravimetric value would be 32.35.

Lastly, if the mercury in the regulator tube be brought to the mark 25, a gas or mixture of gases in the measuring tube will have the volume which it would occupy in the standard-dry state. In this form the instrument is merely a gas volumeter, as described by Lunge, and may be employed for ordinary gas analyses.

From a number of experiments which the author has made, he concludes that the maximum error of the instrument is identical with the error of reading a 50 cc. gas burette with the eye alone, *i.e.*, 0.05 cc., corresponding to one-twentieth of a milligramme in weight.

The gravimetric instrument is designed to fulfil a variety of purposes for which Lunge employs a number of gas volumeters, with a special graduation for each gas, and the author concludes, from his experimental results, that it will fulfil these purposes equally well. Unlike Lunge's specially graduated gas volumeters, it makes no claim upon the skill of the instrument maker beyond that of carrying out the ordinary graduation in cubic centimetres with which he is familiar.

In analytical processes in which the weight of the gas evolved from a weighed quantity of substance has to be determined, the instrument ought to be of service. It is sufficiently accurate for technical purposes, and even for some scientific purposes, such as the absolute determination of nitrogen in organic substances, and the determination of the weight of displaced air in Victor Meyer's vapour density method, purposes for which Lunge has employed his gas volumeter. —F. R. J.

A Spectro-Saccharimeter. P. Glan. *Neue Zeits. Rubenzucker Ind.* 1891, 26, 138—141.

The apparatus Fig. 1 serves to determine the rotatory power, for any desired ray of the spectrum, of all substances which rotate the plane of polarised light. The source of light is a petroleum or gas lamp, or the electric light. The instrument admits of greater exactitude than those which employ sodium, or non-homogeneous light, inasmuch as the rotatory power can be determined for the green or blue rays which are rotated through greater angles than is the yellow ray; it is, moreover, independent of the colour of the substance experimented with, so that with sugar solutions decolourisation is unnecessary. Its construction is shown in Fig. 2. The slit s_1 is placed in the focus of the achromatic lens l_1 , and the light, which is concentrated upon s_1 by a short-focus lens, emerges parallel from it, passing through a Glan's polarising prism p_1 , and then through a diaphragm q , the half of which is covered with a thin quartz plate cut perpendicular to its

axis; this rotates the plane of polarisation a few degrees, differing according to the ray. The light now passes through the tube containing the solution under examination, and then through the polarising prism p_2 (analyser), which latter is capable of being rotated, the rotation being measured to the hundredth of a degree by a vernier on a divided circle. After passing through the flint-glass prism

Fig. 1.

A SPECTRO-SACCHARIMETER.

Fig. 2.

DIAGRAM SHOWING PRINCIPLE OF SPECTRO-SACCHARIMETER.

p_1 a spectrum is produced, of which the achromatic lens l_2 projects a minified image on the slit s_2 . This image can then be observed by the short-focus lens l_3 . The lens l_2 also projects an image of q which can be observed by drawing out l_3 and thus bringing it into focus. As the planes of polarisation of the light, after passing through the diaphragm q , are inclined to one another at a certain angle which differs according to the ray, the two halves of q will only appear equally bright when the light passes the polarising prism p_2 so that its plane of polarisation exactly bisects this angle, or is perpendicular to the line which bisects it. The latter position is that from which the smallest deviation causes the maximum difference in the brightness of the two halves; it is therefore that at which p_2 is placed in the measurement. If the angle at which the planes of polarisation of the light after passing through q be represented by α , then when p_2 is turned from the position at which it exactly bisects this angle through a very small angle γ , the relative brightness of both halves will be $1 + 4 \tan^2 \frac{\alpha}{2} \sin^2 \gamma$; on the other hand, when p_2 is turned from the position at which its plane of polarisation is perpendicular to the line bisecting the angle α , through the same angle γ , the relative brightness is $1 - 4 \cot^2 \frac{\alpha}{2} \sin^2 \gamma$. The alteration is greater in the latter case because α only amounts to a few degrees.

The slit s_1 is first illuminated with sodium light, and the slit s_2 placed at 6 cm. from the lens l_2 , this being the focus of the latter; the lens l_3 is then drawn out until s_2 is discernible. s_1 is now brought within such a distance of l_2 that its image is clearly seen through s_2 ; s_1 is generally adjusted to a width of $\frac{1}{4}$ mm., and s_2 made wide enough to admit its image. The latter completely fills s_2 when the small Kepler telescope is brought to the requisite position by rotating it round the axis of the cylinder containing the flint-glass prism p_1 . Both the tube containing the slit and the telescope can be adjusted by screws so that the image of s_1 occupies the centre of the field of vision, and the light

passes axial through p_2 . By rotating p_2 the image of s_1 may be completely extinguished, and if the lens l_1 be now drawn out till q appears, it is easy to find, by rotating p_2 , that position at which the two halves of the field are equally bright, and a movement of a few hundredths of a degree from this is sufficient to render one half darker than the other. The slit s_1 is next illuminated with white light, and after adjusting the slits, l_3 is drawn out until q is in focus, when it appears in that colour corresponding with the portion of the spectrum which falls upon s_2 . To characterise the colour l_3 is pushed in, and s_1 illuminated with lithium, sodium, thallium, strontium, and rubidium light, and when the image of s_2 appears, the position of the Kepler telescope, as indicated by the vernier attached to the edge of the cylinder, is noted for each of these lights. Another method is to make s_1 narrow, and illuminate it with sunlight until the Fraunhofer lines are seen in s_2 , the positions of the telescope for these being then noted as just described. A sufficient number of fixed positions of the telescope is thus obtained at which homogeneous colours pass through s_2 , and rotatory powers may then be determined for these with the instrument.

The spectro-saccharimeter requires a bright light, and the author employs a petroleum lamp of 36-candle power provided with a condenser; this concentrates the light from the round flame on a small circular opening of 2 cm. diameter, which is placed as near as possible to the slit s_1 of the instrument. The condenser is constructed of sheet iron, having conical projections at the back and front, the widest portions of the cone being 10 cm.; the posterior cone is closed, and both are lined with German silver. The lower portion of the condenser has a neck perforated to admit air, and the upper portion has a short chimney.

Determinations show that the precision of the instrument is as great with or without the tube filled with liquid, but care must be taken that the two ends of the tube are parallel, as when they are not the tube filled with liquid acts as a prism, and shifts the spectrum so that the colour passing through s_2 is altered. The tubes are tested as follows:— s_1 is illuminated with sodium light, and its image rendered visible by pushing in l_3 ; on now interposing the tube filled with liquid and rotating p_2 to the requisite amount, the image of s_1 should not have shifted, if the ends of the tube be parallel.

For analytical purposes the author advises the use of green light, which is very pleasant to the eyes, the instrument being put into adjustment with thallium light as above described. The spectro-saccharimeter may also be found of service in general investigations of rotatory dispersion and in all the applications of optical rotation to quantitative analysis.—A. R. L.

The most Convenient Form of the Gas Volumeter. G. Lunge. Zeits. f. angew. Chem. 1891, 410–412. (See this Journal, 1890, 547.)

This apparatus having been constructed in a great variety of forms, this is a discussion as the most convenient one for general use. The author concludes that except in the case of technical laboratories, where only one substance is examined and where the measuring tube should be graduated so as to give direct percentages, it is best to have two of these apparatus, one with a 150 cc. bulb tube with a wet "reduction tube" and the other with a straight 50 cc. measuring tube with a dry "reduction tube." It is to be noticed that dry gases can be measured in a gas volumeter provided with a "wet" reduction tube by fixing the 100 cc. mark of the latter as many millimetres lower than the mercury in the measuring tube as corresponds to the tension of aqueous vapour at the working temperature, and *vice versa*.—F. H. L.

Colour-Photometry. Captain Abney. Proc. Chem. Soc. November 19, 1891.

ACCORDING to the author, the colour of a body, when viewed in a light of standard quality, is known when (a) its

luminosity, (b) its hue and (c) its purity, or the extent to which it is freed from admixture with white light, are known and expressed by numbers.

The luminosity of a colour can be given in absolute number by referring it to the standard of white. Thus, if white light fall on a coloured surface and on a surface of some standard white, the luminosity of the former may be expressed in terms of that of the light. The comparison is easily accomplished by causing the light falling on the white surface to be rapidly alternately made brighter and darker than that falling on the coloured surface. This can be done by interposing in the beam falling on the white surface rotating sectors with apertures which open and close at will during rotation. The point of equal luminosity can be found by this plan within 1 per cent. The author uses a zinc oxide surface as standard white. By sending the beams through a trough containing water in which mucin is suspended in minute particles, it can be shown that the relation only holds good for the particular light in which it is measured. Hence the necessity for using a standard light.

The luminosity of the light transmitted through coloured translucent bodies can be also measured.

The standard light recommended is that from the crater of the positive pole of the electric light when high illumination is required, or from a petroleum lamp when the illumination need not be so intense.

For measuring the luminosity of light coming through translucent bodies, a white oblong of paper is placed on a blackened card, a square which occupies half this oblong being pierced in the card, and thus half can be illuminated from the back of the card, and the other half by light from the front by placing a rod in the path of the beam to cast a shadow on the first half. The translucent substance is placed close behind the aperture in the card, and the light illuminating the paper, after passage through the translucent medium, measured by altering the illumination of the other half lighted from the front.

The luminosity of the pure spectrum colours may be measured by what the author calls the colour patch apparatus, which is described in the *Phil. Trans.* 1886, and in his work on "Colour Measurement and Mixture." It essentially consists of a collimator, two prisms, a lens, and a camera on the screen of which a spectrum is brought to a focus. This screen is removed for experiments, and a collecting lens used to recombine the spectrum, and to form an image of the last surface of the second prism on a screen some 4 ft. off. A slide with a split passed through the spectrum causes the white patch to become a colour patch of monochromatic light due to the particular ray traversing the spectrum slit. The white light with which the colour is compared is obtained from the light coming through the collimator and reflected from the first surface of the first prism; by means of a mirror and lens, it forms a patch equal in size to, and which can be caused to overlap, the coloured patch, or to lie alongside of it. In the first case, a rod placed in the path casts two shadows, one of which is illuminated by the colour and the other by the white light; rotating sectors in the path of the latter allow the luminosity to be compared. The light used is the electric light, an image of the crater of the positive pole being formed on the slit of the collimator.

The luminosity of a colour is not the same when viewed from all parts of the eye. The centre of the eye is that with which observations are usually made; hence the luminosity should be measured with that part of the retina, and it is advisable that no more than 6° of angular measure from the eye should be compared.

The action of the yellow spot was then alluded to.

The luminosity of any pigment on paper can be found by rotating it with two of the three colours: red, emerald-green and ultramarine.

These three make a grey which matches a grey formed of black and white. If the luminosity of the three have been accurately determined, by substituting the pigment whose luminosity is required for one of them, another grey can be formed to match a grey consisting of black and white. After measuring the angular aperture of the sectors, the luminosity is determined by calculation; the result is found

to agree with the measurement made by the direct method. This is one of the many proofs that the measure of luminosity obtained in the manner described is correct, and not a mere accident (compare this Journal, 1890, 10—15).

The colour of a pigment can be referred to the spectrum colours by measuring the absorption. In the case of transparent bodies, this is best done by using a double-image prism at the end of the collimator so as to form two spectra on the camera screen. By adjustment, these may be caused to be so exactly one over the other, that the same colour will pass through a slit in them. After emergence from the slit, the rays from the top spectrum are diverted by a right-angle prism, and caught by another which sends them through a lens on to the screen, forming a patch. Another patch as usual is formed by the rays from the bottom spectrum. By placing the transparent body in the path of one of these rays, the absorption can be measured by equalising the brightness of the patches by the sectors and noting the apertures.

To measure the absorption of pigments an easy plan is to rotate black and white sectors together with variations in the amount of white, and to cause the colour patch to fall partly on them and partly on the pigment. The colour is varied till it is seen that the grey disc and the pigment reflect the same amount of light.

By both these plans templates can be cut out, which, when rotated in the spectrum, give the exact colour of the pigment on the screen; hence this is a reduction of the true colour to absolute numbers, since the colour can be reproduced from a reference to a note book. It is to be remarked that the measures are unaffected by any defect in the eye of the observer or by the kind of light in which they were effected.

The mixture in varying proportions of red, green, and violet of the spectrum makes white. This can be shown by placing three slits in standard positions in the spectrum, and altering their apertures till a match be made with a patch of white light alongside.

Any other colour can be matched by the mixture of the same three colours (compare this Journal, 1890, 11).

Since three colours will make white, and the same three colours will make a match with an impure colour, every colour in nature can evidently be matched by mixing not more than two of these colours with a certain proportion of white light; and if these colours be red and green, or green and violet, the colour can be matched by one spectrum colour and white light, since there is some intermediate colour which has the same hue as the mixture of these two colours. Hence any colour, except purple, can be referred to some spectrum colour, together with a certain proportion of white light. In the case of purple the colour may be expressed as white light, from which the complementary colour is eliminated. Hence any colour, whatever may be expressed in terms of white light and one spectrum colour, the latter in wave lengths, and the former in percentage of luminosity.

Light coming through properly packed specimens of red, blue, and green glass, and overlapping, may also be made to match a colour.

If the dominant wave-lengths of the colour of these three glasses be known, and also the amount of white light mixed with it, these measures can be noted in terms of these three glasses; and, further, it is possible, by mixing the light coming through the three glasses in various proportions, to obtain a spectrum colour mixed with white light for each such mixture. Hence this is a substitute for the spectrum itself.

Any colour can be reproduced with three rotating sectors of red, green, and blue when certain proportions of white or black, or both, are mixed with one or other. If the dominant wave-lengths and the proportion of white light mixed are known of each such colour, the pigment whose colour is to be determined can be expressed in numbers as before, and in terms of spectrum colours it desired.

In conclusion, the author claims to have demonstrated that the reference of colour to numbers is not only possible but easy, and that, to chemists especially, the application is one of almost capital importance. O. H.

PATENTS.

An Improvement in Mercury Vacuum Pumps. E. C. C. Baly, London. Eng. Pat. 20,309, December 12, 1890. 6d.

In this invention two small subsidiary chambers are connected with each other by the short neck of a syphon dipping into mercury. The lower chamber is similarly connected with the vacuum chamber, and the upper chamber is in communication with a mechanical air pump. By this improvement the use of valves and taps, which are difficult of construction and so liable to leak, are avoided.

The pump is worked as follows: A preliminary exhaustion through F having been obtained by mechanical means the mercury is driven into the top chamber B. On lowering the mercury the reduced pressure in B will not be sufficient to drive any mercury back over the syphon E. Thus a Torricellian vacuum will be formed in the middle chamber A. Similarly a second vacuum will be formed in the large chamber G separated from that in A by the intermediate syphon D, and any air which is drawn into G is discharged by the rising mercury into the Torricellian vacuum in A, thus suffering the least possible compression in the chamber G. The mercury reservoir is suitably connected to C and the vessel to be exhausted to tube V. The tubes H, K, simply act as an overflow from B.—O. H.

Improvements in Ore-Sampling Machines. H. Le Roy, Bridgman, Blue Island, U.S.A. Eng. Pat. 13,198, August 1, 1891. 8d.

INORGANIC CHEMISTRY.— QUALITATIVE.

Detection of Nitrates and Chlorates. M. Forbes. Chem. News, 1891, 64, 105.

To detect nitrates when mixed with chlorates, the mixture, placed in a test tube along with dilute sulphuric acid and copper foil, is heated in a bath of boiling saturated salt solution; the chlorate is first decomposed, attacking the copper and evolving greenish chlorous gas, subsequently the nitrate is decomposed, also attacking the copper, but evolving red nitrous fumes. In the absence of chlorates, but in the presence of bromides or iodides, nitrates may be detected by heating with lead foil and strong hydrochloric acid, the nitrate decomposes, forms lead nitrate, the presence of which is indicated by the precipitation of lead chloride.

INORGANIC CHEMISTRY.— QUANTITATIVE.

The Volumetric Estimation of Carbon in Iron and Steel, and the Determination of Carbonic Acid in Aqueous Solution. G. Lunge and L. Marchlewski. Zeits. f. angew. Chem. 1891, 412—414.

The apparatus devised by the authors and described in this Journal, 1891, 658, is employed for this purpose, by the substitution for the decomposition flask A (p. 658) of a flask holding 200 cc., into the side of which a funnel provided with a stop-cock and holding about the same amount is fused, the tube from which reaches to the bottom of the flask and is drawn out to a fine point; to the neck of the flask, the inner tube of an inverted condenser is ground, the other end of which is connected by another ground joint with the tube *d* (*loc. cit.*). Into the flask is weighed out from 0.5 to 5 grms. of the iron or steel and 10 times the amount (in cc.) of a saturated solution of copper sulphate added; at the end of the action the flask is connected up with the cooler and the gas volumeter, and the whole exhausted in the manner previously described. 5 to 50 cc. of a solution of chromic acid (1:1) is added through the funnel, and then 130 cc. of sulphuric acid, sp. gr. 1.65, saturated with chromic acid, or in the case of samples containing small amounts of carbon only, 70—75 cc. of an acid of sp. gr. 1.71. The funnel is rinsed out with 5—30 cc. of weak acid (sp. gr. 1.10), and the cock between it and the flask closed. The cock on the volumeter is then opened and the flask warmed slightly. When all the carbon is oxidised, 1 or 2 cc. of hydrogen peroxide are added through the funnel to drive out the last traces of carbonic anhydride, and finally the flask and tubes are filled up with warm water. The total amount of gas in the measuring tube is noted, the carbonic acid absorbed in the Orsat's tube and the residue measured as before described. Should it be feared that there will not be sufficient gas left to reach below the bulb, some air free from CO₂ should be introduced into the tube B before the absorption takes place. Results given in the original paper show very close agreement with others obtained by the gravimetric method.

For the estimation of carbonic acid dissolved in water the sample is introduced into the flask with a small quantity of pure aluminium or iron wire, and after exhaustion the acid run in through the funnel; this method giving the total amount of carbonic anhydride present. As previously explained the apparatus once set acts as its own barometer, and hence 1 cc. of gas corresponds to 0.000536 gm. of carbon, no correction for temperature or pressure being necessary.—F. H. L.

Estimation of Bromine and Iodine in Presence of Chlorine. E. Nihoul. Zeits. f. angew. Chem. 1891, 441.

The usual proceeding is to precipitate as chloride, bromide and iodide of silver and weigh as such, and then subsequently to convert the whole into chloride by the aid of

chlorine and weigh again. As chlorine is unpleasant and its use at times difficult, the author has examined the question of the possibility of substituting hydrochloric acid gas therefor. He finds that silver bromide is completely transformed into chloride by hydrochloric acid gas, but that for quantities of from 0.1 gm. to 0.4 gm. of silver bromide it is necessary to pass the gas for an hour. The iodide is not completely transformed by hydrochloric acid gas. Now, considering that the whole operation for conversion of bromide into chloride by chlorine lasts only five minutes, and that for the conversion of iodide into chloride only ten minutes, it is evident that substitution of hydrochloric acid gas is not to be thought of here as a substitute for chlorine.

Valuation of Aluminium and its Alloys. F. Regelsberger. Zeits. f. angew. Chem. 1891, 442—446 and 473—478. (See also this Journal, 1891, 387.)

The author gives the following as his complete method of determining the silicon:—4 grms. of clippings are weighed into a deep porcelain dish, covered with a clock glass; 80 cc. of *aqua regia* (30 cc. of nitric acid of sp. gr. 1.35 to 70 cc. of hydrochloric acid of sp. gr. 1.16) are gradually added with care and the whole is warmed. Then with continued boiling about 30 cc. of strong sulphuric acid are added. When acid vapours cease to be evolved, 150—200 cc. of water are carefully added, the clock-glass still being kept on, and finally the precipitate is filtered and well washed. The precipitate is ignited in a platinum crucible direct and weighed. Evaporation with pure hydrofluoric acid is now performed, loss being taken as SiO₂. If now the residue is not of a pure red, it is warmed with a mixture of hydrofluoric acid and a little concentrated nitric acid, and then once more ignited and weighed; the difference between the weight now and the previous weighing is due to silicon. The introduction of sulphuric acid in the foregoing operation is necessary in order to get a precipitate which is sufficiently well matted to filter well.

VALUATION OF FERRO-ALUMINIUM.

(a.) *Estimation of the Aluminium.*—5 grms. of the material are dissolved in dilute sulphuric acid in a porcelain dish covered with clock-glass and heated on asbestos until acid vapours are evolved; water is then added. Should it be desired to determine the silicon, the solution is made up to 300 cc. and filtered into a dry flask; 100 cc. of this are reduced with bisulphite or with iron wire and nearly neutralised with sodium carbonate solution and then poured into a boiling mixture of 50 cc. of pure caustic potash solution (= 10 grms. of caustic potash) and 40 cc. of pure cyanide of potassium (= 8 grms. of potassium cyanide). If iron has been used for reduction more cyanide is required. Here it is to be noted that a small quantity of iron and manganese (if present) are precipitated. The solution is made up to 500 cc. and filtered. To 300 cc. (equivalent to 1 gm. of the original material) a concentrated solution of ammonium nitrate is carefully added, after which the whole is boiled for about half an hour until the alkalinity has almost disappeared. A drop of ammonium hydrate is now added and the precipitate is filtered off and washed until the washings show no further blue with ferric chloride. The precipitate is ignited in a platinum crucible and weighed as Al₂O₃. Should the precipitate be slightly greenish then iron is present, due to decomposition of the potassium ferrocyanide by continued boiling of the ammoniacal solution. In this case the finely-powdered aluminium oxide is again ignited and then treated in a covered beaker with concentrated hydrochloric acid and titrated, without filtering, with stannous chloride. In the brown precipitate obtained above on boiling with caustic potash and potassium cyanide, the manganese may be determined by igniting and weighing and then titrating the iron (the amount of manganese thus being got by difference).

(b.) *For the Estimation of the Iron.*—In ferro-aluminium the sulphuric acid solution may be reduced with zinc and titrated with permanganate (or the solution used for the aluminium determination may also be taken,

(c.) *Estimation of Manganese*.—This may be performed in a separate solution according to the method of Volhard or of Hampe, or it may be estimated as already indicated under (a).

(d.) *Estimation of Silicon*.—The first residue obtained under (a) consists of a mixture of silicon, silica, and ferric oxide. This may be purified whilst still moist by boiling with caustic potash.

(e.) *Estimation of Carbon*.—This is carried out by oxidising 5 to 10 grms. of the material with chromic and sulphuric acids and weighing the carbon dioxide formed.

(f.) *Estimation of Sulphur*.—In the usual way after solution in *aqua regia*.

(g.) *Estimation of Phosphorus, Titanium, &c.*—These are performed as in the case of pig iron.

Approximate Valuation by aid of Specific Gravity.—When the same materials are used and so long as the conditions of the manufacture remain the same, the specific gravity of the masses of ferro-aluminium made bears a definite relation to the quantity of aluminium contained, the specific gravity is inversely proportional to the amount of aluminium contained. As the raw products vary but slightly in the same class of goods, differences of physical condition need only be taken into consideration, and these are rendered evident in the external appearance of the products, such, for instance, as separation of graphite. According to the process of manufacture of ferro-aluminium the graphite separates from the mass and may be mechanically removed, or it remains evenly distributed in the mass; in the former case, a product is obtained free from graphite, and in the latter a product containing graphite, and so grey to blackish in fracture instead of white. The product free of graphite has, for the same amount of aluminium, a higher specific gravity than the other. In the compilation of empirical tables of the specific gravity and amount of aluminium, these points must be carefully noted.

Estimation of Small Quantities of Aluminium in Iron and Steel the author considers may be most easily and most quickly performed by the potassium cyanide method. The large quantities of reagents required, however, are apt to contain sufficient alumina to introduce considerable errors.

ALLOYS OF ALUMINIUM AND COPPER.

These may be classed under three heads: (a) "aluminium bronzes," consisting for the most part of only aluminium and copper; (b) "aluminium brass," containing a third considerable constituent, zinc; (c) other combinations in company with copper. The most useful aluminium bronzes contain from 5 to 12 per cent. of aluminium, not more; if more than 12 per cent. be present, the alloy becomes brittle and unworkable. Silicon is often purposely added, as it increases the tensile strength; maximum is 2.5 per cent. A good idea as to the character of the alloy may be obtained from its outward appearance and physical properties. An alloy containing less than 3 per cent. of aluminium has almost the colour of copper; with from 3 to 4 per cent. it has the colour of a reddish sample of gold; with 5 per cent. the colour is gold yellow, and with increasing percentage of aluminium the alloy becomes yellow, whilst with 15 per cent. of aluminium the colour is white with merely a tinge of red. Fracture gives also characteristic indications. Aluminium brass contains up to 3.5 per cent. of aluminium. Even 0.25 per cent. of aluminium has a very considerable influence on brass, raising the tensile strength. An alloy with 10 per cent. of zinc and 2 per cent. of aluminium has a high tensile strength, whilst with 40 per cent. of zinc and 3 per cent. of aluminium the alloy is brittle, but a great improvement is again noticed if the zinc be reduced to 33 or 34 per cent. For rapid valuation of these alloys, a specific gravity determination made in conjunction with a qualitative examination may be made to tell whether aluminium bronze or aluminium brass is present, and, if the former, what amount of aluminium and silicon it may be expected to contain. These points are illustrated in the original article by a diagram.

The author makes the following observations regarding quantitative estimations:—*Silicon* (a.) 3–5 grms. of material are dissolved in *aqua regia*, the solution is taken to dryness, and the residue is taken up with hydrochloric acid or evaporated with sulphuric acid. Should the residue be not perfectly white, it is fused with a mixture of sodium and potassium carbonates. (b.) Should tin or lead be present, nitric acid alone is used instead of *aqua regia*, evaporation being subsequently performed with sulphuric acid. The precipitate obtained in this way contains the silicon, the tin, and the lead. It is fused with sodium and potassium carbonates, and then evaporated with nitric acid. SiO_2 and SnO_2 form the new precipitate. The silica may subsequently be determined by evaporation with hydrofluoric and sulphuric acids.

Iron and Aluminium.—(a.) Zinc absent. From the original solution in *aqua regia* the copper is precipitated by sulphuretted hydrogen or sodium thiosulphate, and then the iron and aluminium are separated in the filtrate by pouring the same into boiling caustic potash (after removal of sulphuretted hydrogen, &c.). The cyanide method may also be used, but in this case the alumina precipitate generally contains a little copper. This may be removed, however, by boiling with dilute nitric acid, neutralising with ammonia, and filtering the pure hydrate precipitated. The iron determination here must be made in a special portion of the solution by precipitating with ammonium hydrate, dissolving the precipitate in dilute acid, and titrating with stannous chloride, or after reduction with zinc titration may be performed with permanganate. (b.) Zinc present. The iron and aluminium are first precipitated together by sodium acetate or ammonium hydrate, and then separated as above in (a).

Copper.—Best done by electrolysis. 3–5 grms. of material are dissolved in nitric acid, a little sulphuric acid is added, and the whole is evaporated to a syrup. An aliquot portion (= about a gm.), diluted, is then electrolysed. Before electrolysis it is well to neutralise with ammonia and add 10 cc. of dilute nitric acid for 200 cc. of liquid. By taking this precaution complete precipitation is effected.

Zinc.—Most conveniently estimated electrolytically. Precipitation as phosphate is quick (Lösekann and Meyer, Chem. Zeit., 1886, 729 and 1605; also 1891, 81). Determination with potassium ferrocyanide is also very quick, and is sufficiently exact.

Manganese occasionally finds its way into bronzes. It is obtained in company with the iron in separation of iron and alumina by caustic potash.—T. L. B.

New Method for the Quantitative Separation of Iron, Aluminium, and Chromium. C. Marchal and J. Wiernick. Zeits. f. angew. Chem. 1891, 511–513.

The authors propose this method as being greatly superior in delicacy and feasibility to those hitherto in use, which is based on the employment as reagent of freshly precipitated manganese peroxide, prepared by the double decomposition of equivalent quantities of manganese sulphate and potassium permanganate.

The oxides are best dissolved in sulphuric acid, and the excess of acid is neutralised by adding sodium carbonate until a slight permanent precipitate is formed, which is re-dissolved by addition of a drop of acid. The hydrated manganese is then added, and the whole is boiled for 10 minutes. After allowing the precipitate to subside a drop of the clear solution is tested with ferrocyanide, and if it be found free from iron, enough manganese peroxide has been used; otherwise more must be added and the boiling and testing repeated. The precipitate now contains all the iron, and the solution all the aluminium and chromium, from which the alumina is precipitated by heating with ammonia. The chromic acid in this filtrate is reduced to chromic oxide and then precipitated with ammonia.

The precipitates containing the ferric oxide and alumina are separated from accompanying manganese oxides by solution in hydrochloric acid and precipitation with sodium acetate in the ordinary way.

The following results show the accuracy of the separation:—

	Employed.	Found.
1. Fe_2O_3	Grms. 0.012	Grms. 0.016
Al_2O_3	0.009	0.005
Cr_2O_3	0.100	0.104
2. Fe_2O_3	0.180	0.182
Al_2O_3	0.0582	0.0584
Cr_2O_3	0.1714	0.1708
3. Fe_2O_3	0.072	0.072
Al_2O_3	0.29	0.293
Cr_2O_3	0.070	0.0708

—W. M.

Antimony Pentasulphide. T. Wilm. Zeits. Anal. Chem. 1891, 30, 428—446.

It is a well-known fact that different samples of the "golden sulphide of antimony" used in vulcanising rubber often produce widely different results, some being indeed useless for this purpose, owing to the dark colour of the product. These differences have usually been explained by considering that some varieties of the commercial sulphide consist almost entirely of the compound Sb_2S_5 , while others, the inferior ones, are varying mixtures of trisulphide, pentasulphide, and free sulphur in such proportions as to yield on analysis figures corresponding to the true pentasulphide. For this reason the usual process employed in examining the commercial substance has been to estimate the amount of sulphur soluble in carbon bisulphide. The author's experiments, however, show that this process is absolutely unreliable, seeing that samples of pure pentasulphide prepared by different methods yield on extraction different amounts of sulphur to the solvent.

Two samples of the golden sulphide, (a) and (b), were examined; (b) behaved towards carbon bisulphide exactly as a pentasulphide prepared from pure crystallised Schlippe's salt ($\text{Na}_3\text{SbS}_4 + 9 \text{H}_2\text{O}$), yet was useless for vulcanisation. (a) contained more free sulphur, and might be considered a mixture of trisulphide and sulphur, and yielded vulcanised products of very superior quality. On treatment with water, (a) was found to be much more readily miscible than (b), and examined under the microscope appeared to contain some semi-transparent crusts resembling sulphur, while (b) was perfectly homogeneous. The aqueous solutions, which in both cases were neutral to test papers, after acidifying with nitric acid, gave with barium chloride, (a) a faint cloudiness, and (b) a yellow colouration, and afterwards a brownish-black flocculent precipitate; with silver nitrate, (a) a strongly-marked cloudiness, and (b) no reaction. Extracted with tartaric acid solution, (a) gave on treatment with sulphuretted hydrogen an immediate yellow colour, and on heating a considerable precipitate of sulphide, (b) containing only traces of dissolved antimony. On shaking for some time with concentrated ammonia at ordinary temperatures, both yielded a yellow liquid with much free sulphur and a whitish insoluble residue, but while this, in the case of (a), contained, even after 14 days, much undecomposed red antimony sulphide, no trace of any red substance was found in the residue from (b) after two days. Heated in air both samples behaved alike, the first appearance of decomposition being at about 180° , no darkening in colour occurring at 110° , as stated by Classen (Ber. 16, 1071).

For the quantitative estimation of the total amount of sulphur present, the best method is that of Carius, which consists in heating the substance with fuming nitric acid under pressure. From 0.2—0.4 gm. of the pentasulphide is weighed out into the tube to be sealed up, and about 1 cc. of fuming nitric acid introduced into a smaller tube made of very thin glass and drawn out at one end to a very fine

opening. This latter is then dropped into the larger tube, which is sealed up and the acid set free by breaking the inner tube by a blow. After the action is over, the tube is heated to about 130° for two or three hours; the end is then broken off and a small quantity of water introduced with care, a considerable amount of gas being set free. It is next filled up with strong hydrochloric acid and heated on the water-bath till the white residue is dissolved. The tube is washed out into a porcelain basin, evaporated down, to remove the nitric acid, a little more hydrochloric acid added, and then tartaric acid solution. If successful a perfectly clear liquid should result which is not rendered turbid by the addition of water. This being the case, the sulphuric acid is precipitated with barium chloride in the ordinary way.

If sufficient material be at hand, the extraction of the free sulphur may take place in a Soxhlet's apparatus, about 5 grms. being treated for two or three hours; otherwise 0.5 to 1.0 gm. of the substance should be treated in a small Erlenmeyer's flask two or three times with 10–15 cc. of carbon bisulphide, the flask being tightly corked and heated on the water-bath with constant shaking, the liquid being filtered through a tared paper dried at 110° . The flask must finally be rinsed out with alcohol, the finer particles sticking tightly to the walls, for which reason it is impossible to conduct the operation by boiling with an inverted condenser, owing to the bumping of the liquid. After the residue is washed with alcohol, it is dried at 100° – 110° and weighed.

To prepare pure antimony pentasulphide, some freshly-crystallised Schlippe's salt was dissolved in water, and poured in a thin stream into so much dilute sulphuric acid that the mixture had a faintly acid reaction. To avoid as much as possible the presence of free sulphur from the decomposition of the sulphuretted hydrogen, the latter was removed from the liquid as fast as it was formed by passing through it a current of pure carbonic acid gas: this precaution, however, was afterwards found to be unnecessary when acid liquids were employed. The voluminous precipitate settled well, and was washed by decantation; towards the end of the process a colloidal modification was formed, and could only be removed from the wash-waters by the addition of a small quantity of hydrochloric acid. The substance was finally brought on to a filter-pump, washed with alcohol, and dried over sulphuric acid. This product in common with all the others prepared by the action of acids on alkaline liquids was found to shrink very much in drying, yielding a dark brown brittle substance resembling ferric hydrate. Samples of pentasulphides were also prepared in different ways from the substance known as *Kalium stibicum*, by the addition to the filtered aqueous solution of sulphuretted hydrogen either alone or in the presence of tartaric and hydrochloric acids, a second precipitate (see table) being obtainable from the first decanted liquor by the addition of more sulphuretted hydrogen while warm. From the commercial *liq. stibii chlorati*, by saturation with chlorine, addition of tartaric acid, followed by sulphuretted hydrogen, another variety was obtained, and lastly the commercial antimony pentachloride (*stib. perchlorat.*) was employed. The characteristics of these different substances are shown in the Table (I.) on following page.

It is probable that a partial explanation of the irregularities noticeable in the last column may be found in the not generally known volatility of antimony pentasulphide at temperatures only slightly above 100° . On heating in an air-bath to about 110° , not only does this substance volatilise as such, as may be seen by placing a watch-glass over one of the openings of the bath, and examining the sublimate under the microscope, but at the same time, a partial oxidation takes place, the bath becoming filled with a dense white fume, consisting of an oxide. The sample referred to in Table I. as "first precipitate" lost in 28–30 hours at temperatures varying from 100° to 120° , 8.4 per cent. of its weight; that from Schlippe's salt lost 4.6 per cent. in 9–10 hours at 100° – 110° , and the commercial sample (b), 1.7 per cent. in four hours at 105° – 110° . After exposure to heat in this manner, free oxide was found on extraction with tartaric acid, whereas previously, the sample prepared from Schlippe's salt contained nothing

soluble. Antimony trisulphide heated under similar conditions to 120° suffered no loss of weight.

These results show that Bunsen's process (*Annalen*, **192**, 305) for the estimation of antimony in presence of arsenic, which consists in the precipitation of the former by sulphuretted hydrogen in the oxidised solutions and the washing of the precipitate in water, alcohol, four amounts of carbon bisulphide, and finally alcohol, and then drying at 110° and weighing as Sb₂S₃,—yields faulty results; and to see whether this could be avoided by drying over sulphuric acid, some pentasilphide was prepared in the way given by him for the analysis, and also two fresh samples from Schlippe's salt (*a*) and (*b*), the first exactly as previously described, but without the use of alcohol in the washing, (*b*), without the carbonic acid but with alcohol. These three samples before drying were extracted with cold CS₂ and in each case yielded a considerable amount of free sulphur, and on further treatment with the hot solvent still more free sulphur was obtained. Dried as described above, their analyses are given in Table II.

—F. H. L.

Electrolytic Determination of Metals as Amalgams. G. Vortmann. *Ber.* 1891, **24**, 2749—2765.

In the electrolytic estimation of metals it is necessary that the metal form a well-adhering film on the platinum dish, which is used as electrode.

This film must be sufficiently adherent to admit of its being washed. Some of the metals determinable by this method adhere well only when present in small quantities; such metals are antimony, bismuth, cadmium, lead and manganese. For the purpose of improving the character of the film it was proposed by Luckow (*Chem. Zeit.* 1885, 338; see also *Zeits. f. Anal. Chem.* 1880, 15) to add a quantity of mercury so that an amalgam might be deposited. Wolcott Gibbs (*Chem. News*, **42**, 291) employed mercury as negative electrode, dispensing with a platinum dish, and using a glass beaker. It is known that mercury may be deposited satisfactorily from acid solutions, from solutions in cyanide of potassium, and from ammoniacal solutions of the sodium pyrophosphate double salt; the author shows also that it may be perfectly well deposited from the ammonium oxalate double salt, and from solutions of its salts in potassium iodide, in sodium sulphide, and in ammonia in presence of tartaric acid.

Determination of Zinc.—Luckow recommended that the depositing of zinc as amalgam should be performed in a solution slightly acidified with sulphuric acid. The correctness of this method the author confirms, but he furthermore points out that a large excess of free acid is capable of preventing deposition altogether. In ammonium oxalate solution, and in ammoniacal solution in presence of tartaric acid the amalgam deposits well; in the former case not more than 3 parts of mercury must be present to 1 part of zinc, otherwise the deposit is not fixed; in the case of the ammoniacal solution at least three times as much mercury as zinc should be present—excess of mercury not being detrimental. Unfortunately the platinum dish is apt to be very considerably attacked in this method of zinc deposition, and it seems better to adopt the method, hitherto used, in which the platinum dish is previously coated with copper or silver.

Determination of Cadmium.—The ammonium oxalate method is only adapted to the determination of small quantities of cadmium, as the cadmium ammonium oxalate is less soluble in water than the corresponding zinc salt. For cases where the cadmium to be deposited exceeds 0.3 grm., the following method is recommended:—The solution of the cadmium and mercury salts is mixed with about 3 grms. of tartaric acid, and then ammonia is added until the solution smells strongly of the same; the whole is diluted with water and deposition carried out.

Determination of Lead.—In acid solutions this may be carried out as follows:—The lead salt and mercuric chloride are dissolved in water, 3 to 5 grms. of sodium acetate are added, and a few cc. of a strong solution of potassium nitrite; the precipitate formed is dissolved in acetic acid and deposition proceeded with. The great difficulty in lead estimations is the liability to formation of peroxide of lead on the positive pole; presence of nitrous acid, as provided in the foregoing method, is instrumental in preventing this. Deposition of the lead amalgam may also be performed from a dilute nitric acid solution, to which potassium nitrite is continually being added slowly; the acetic acid method is, however, much more convenient. Lead may also be determined in alkaline solution obtained by dissolving the lead salt and mercuric chloride in water, adding tartaric acid, and then caustic soda in excess; the brown precipitate formed is easily dissolved in potassium iodide. During deposition no peroxide separates (as is the case if an ammoniacal solution be used). As the amalgam obtained is easily oxidisable in moist condition, the results given are high and consequently the method is made to serve rather as a separation of lead from other metals, such as tin and arsenic, than as a means of direct estimation.

Determination of Bismuth.—This is best performed in acid solution, since bismuth oxalate is insufficiently soluble in ammonium oxalate solution. Excess of acid must be present during deposition so as to prevent precipitation of basic salts, and yet too large an excess is not desirable;

hence the author, instead of a large excess of hydrochloric acid, uses potassium iodide, since bismuth iodide dissolves in excess of potassium iodide and no basic salt separates on dilution.

Determination of Antimony.—This estimation has hitherto been difficult to perform by electrolytic method, and its estimation at all has been limited to small quantities; the amalgam method of deposition, however, renders electrolytic estimation of antimony comparatively easy. For every part of antimony there must be in solution about two parts of mercury, though a larger quantity of mercury is not detrimental. The antimony amalgam deposited is steel-grey in appearance, and is unaffected by standing in the air. The estimation is not limited to small quantities. An ammoniacal solution of antimony (containing tartaric acid) gives no deposit whatever of amalgam; mercury alone is obtained, so that here a method of separating antimony from lead, bismuth, and other metals presents itself.

Deposition of Arsenic as Amalgam.—In the electrolysis of arsenic solutions it was found that arseniuretted hydrogen was given off; addition of potassium iodide, however, was instrumental in bringing about decomposition of such arseniuretted hydrogen with consequent deposition of most of the arsenic in the form of a dark brown amalgam. The quantitative deposition has not yet been obtained.—T. L. B.

Estimation of Molybdic and Tungstic Acids. E. F. Smith and R. H. Bradbury. Ber. 1891, 24, 2930—2936.

AN investigation is here made of the use of various salts in quantitative estimations of molybdic and tungstic acids. Both may be satisfactorily determined in neutral solution, the authors find, by precipitation with barium chloride. Precipitation is performed in the hot, and the whole is allowed to stand for a considerable time before filtering; washing of the precipitate must be performed with cold water, otherwise low results are obtained. The strontium salts are not suited to the quantitative estimations in question. Molybdic acid, but not tungstic acid, may be determined as the calcium salt in presence of alcohol, but the details of the process are much more considerable than in the case of the barium salt. Molybdate of lead forms a white granular precipitate, which is soluble in nitric acid and caustic soda. On heating, however, it takes a yellow colour, and is then unacted on by these reagents. Determination as lead salt is found to be excellent, as previously reported by Zettnow (Jahresb. 1867, 267), and Chatard (Amer. J. Sc. and Arts I. [3], 416). Lead tungstate forms a precipitate, which is extremely difficult to filter; the difficulty is to a certain extent modified by addition of ammonium nitrate. The calcium salts are capable of being used for the estimation; but the silver salts cannot be used, on account of decomposition ensuing on heating.

—T. L. B.

Oxidation of Copper Glance by Aid of the Electric Current. E. T. Smith and D. L. Wallace. Ber. 1891, 24, 2938—2939.

PREVIOUSLY the metallic sulphides with one exception, copper glance or rednithite, have been oxidised by the aid of the electric current (this Journal, 1890, 971). The authors have now succeeded in completely oxidising this sulphide also by the method in question. With 0.1 grm. of mineral they used 35 grms. of potassium hydrate; the oxidation was complete in 40 minutes.—T. L. B.

A New Method for the Quantitative Separation of Manganese and Nickel, Manganese and Cobalt, and of Manganese, Nickel, and Cobalt. P. Jannasch and C. J. Franzek. Ber. 1891, 24, 3204—3205.

THIS is a preliminary notice of a new method for separating the above metals, the details of which the authors propose to give at a future date. Following up the method of

MacGregory with one of the authors (Jour. Prakt. Chem. 1891, 43, 402; this Journal, 1891, 659), for the separation of manganese and zinc, viz., by the precipitation of the manganese by hydrogen peroxide from a strongly ammoniacal solution of the metals and in the presence of a large amount of ammonium chloride, the authors find that manganese and nickel can be separated accurately and conveniently by the same process. The separation of manganese and cobalt cannot, however, be effected in this way, as the precipitate of hydrated manganese dioxide invariably carries down with it a considerable quantity of cobalt. By employing a solution of the double cyanides of manganese and cobalt rendered alkaline by potassium hydrate, hydrogen peroxide produces the precipitation of the manganese in a state absolutely free from cobalt. The separation of nickel may be effected equally well in the same way, and likewise the separation of nickel and cobalt from manganese when the three metals are present together. The authors mention that the reagents have to be used in certain definite proportions, and that the observance of certain precautions are essential to the carrying out of the method successfully, and these details they promise to give later.—H. S. P.

On the Solution of Chrome Iron Ore by Hydrochloric Acid under Pressure. P. Jannasch and H. Vogtherr. Ber. 1891, 24, 3206—3208.

ABOUT 1 grm. of the finely-powdered mineral is sealed up in a tube of potash glass with 2 grms. of ammonium chloride and 10 cc. of hydrochloric acid (1 vol. of acid 1.119 sp. gr. to 1 vol. of water) previously saturated with ammonium chloride. The tube is then heated to a temperature of from 250° C. to 290° C. for 8—10 hours. Complete decomposition and solution of the ore take place under these conditions. The residue in the case of three varieties of chrome iron ore, after removing the silica by evaporation with hydrofluoric acid and sulphuric acid, was 0.17 per cent., 0.37 per cent., and 0.69 per cent. respectively, whilst in a fourth instance, where selected crystals of Maryland chrome iron ore sand were used, and no special care was taken to pulverise the mineral very finely, the residue weighed 1.22 per cent., some of which in this case consisted of undecomposed ore. The authors state that the length of time of heating, the temperature to be used, and the effect of using quite concentrated acid require further investigation.—H. S. P.

The Ammonia Process of Water Analysis. R. Haines. Journ. Franklin Inst. 1891, 131, 461—467.

IN conducting this process the author finds it best to use half a litre of water, or when the water is very impure a smaller quantity diluted to half a litre with pure distilled water, the distillation being performed in a retort of one-third to one-half gallon capacity, supported at the neck by a large retort clamp, but not resting on a ring. The neck is inclined upwards at an angle of 25°, the end being either brought into close contact with the end of the inner tube of the condenser under the rubber tubing or bent down and fitted into the condenser tube, in either case the rubber tubing is tied down over the joint to prevent leakage. If a Liebig's condenser only is used the current of water should be so rapid that its temperature is not materially raised; if the temperature of the water supply is over 50°—60° F. it should, previous to use, be cooled by ice. A better plan is to attach to the end of the Liebig tube a Mohr's glass vertical coil condenser cooled by ice. The author finds that polluted waters containing large quantities of free ammonia yield four-fifths of their total ammonia in the first 50 cc. of distillate instead of three-fourths as stated by Wanklyn.—S. B. A. A.

Heat of Evaporation of Liquid Ammonia. H. von Strombeck. Journ. Franklin Inst. 1891, 131, 470—476.

See under VII., page 1005.

New Method for the Analysis of Tin-Ores, and for the Separation of Copper and Cadmium. J. S. C. Wells, School of Mines Quarterly, 1891, 12, 295—297.

Tin Ore.—This method consists in heating the finely-powdered tin-ore with zinc, hydrochloric acid, and platinum foil with frequent agitation. The tin is rapidly reduced to the metallic state, and when the reaction is judged to be over it is dissolved in hydrochloric acid, filtered, and the gangue again tested in the same way. The tin in solution is determined by any of the usual methods. The metallic tin may also be dissolved in ferric chloride and determined volumetrically.

Separation of Copper and Cadmium.—To the neutral solution of these metals (ammonium salts being absent) sodium thio-sulphate is added until the solution becomes colourless, the cadmium is then precipitated as carbonate by the addition of sodium carbonate and filtered off; on acidifying the filtrate with hydrochloric acid, and boiling the copper is precipitated as sulphide. To apply this method in the ordinary course of analysis, the solution after removal of the bismuth must be evaporated to dryness and ignited to remove ammonium salts.—S. B. A. A.

The Iodometric Estimation of Chlorates. G. McGowan, Proc. Chem. Soc. 1891, 169.

ATTENTION is called to Finkener's statement, that when Bunsen's method is applied to chlorates, less than the theoretical amount of chlorine is evolved. Experiments are then described, made in accordance with the method, which corroborate the results of de Koninck and Nihoul, and prove the accuracy of the Bunsen method; Finkener's error doubtless arose from a slight loss of chlorine. The author emphasises the importance of carrying out all such determinations in an apparatus in which the chlorine does come into contact with india-rubber.

ORGANIC CHEMISTRY.—QUALITATIVE.

The Examination of Phenacetin for p-phenetidin. F. Goldmann. Pharm. Zeit. 1891, 36, 298.

THE author finds that the iodine test for *p*-phenetidin, which Reuter (Phar. Zeit. 36, 192; this Journal, 1891, 799) states is far less sensitive than the chloral-hydrate method, is improved by being carried out in the following manner: 0.5 gm. of phenacetin is dissolved warm in alcohol and 5 cc. of a solution of iodine in potassium iodide (0.01 gm. I in 200 cc.) added. The solidified mixture is heated to the boiling point until solution is complete, when the presence of *p*-phenetidin is shown by the rose-red colour of the solution. The colour is more pronounced when the phenacetin has again separated out.—F. H. L.

The Use of Lacmoid in Estimating the Affinities of Organic Acids. F. Röhm and W. Spitzer. Ber. 1891, 24, 3010—3015.

WHEN a solution of an organic acid is titrated with soda the liquid turns red lacmoid paper blue, before all the soda theoretically required to convert the acid into normal salt has been added. Such a mixture, which is slightly alkaline to red paper, is, however, still strongly acid to blue lacmoid paper, and more soda must be added—although usually not the full theoretical amount—before the liquid ceases to affect blue paper. Under these circumstances, calling the free acid present in the liquid S_1 and the combined acid (the amount required to form normal salt with the soda added) S_2 , the authors show that the ratio $\frac{S_1}{S_2}$ varies with different acids, and is inversely proportional to their respective affinities for alkali. To this ratio the name "*Coefficient of neutralisation*" is given. Below are given the results of experiments with various acids:—

10 cc. of a $\frac{N}{10}$ Solution of each of the following Acids taken.	Volume of $\frac{N}{10}$ Soda required to make the Solution Alkaline to Red Lacmoid Paper.	Ratio of Free to combined Acid.	Volume of $\frac{N}{10}$ Soda required to cause disappearance of Acid Reaction to Blue Lacmoid Paper.	Ratio of Free to combined Acid.	Volume of $\frac{N}{10}$ Soda required to render Liquid Alkaline to Litmus, Phenolphthalein, &c.
Formic acid	3.70	7.9 : 13.0	9.55	0.45 : 9.55	10 cc.
Acetic acid	1.70	9.0 : 1.70	8.5	1.5 : 8.5	
Propionic acid	0.9	9.1 : 0.9	8.4	1.6 : 8.4	
Butyric acid	0.8	9.2 : 0.8	8.35	1.65 : 8.35	
Isobutyric acid	0.75	9.25 : 0.75	8.35	1.65 : 8.35	
Valerianic acid	0.85	9.15 : 0.85	8.5	1.5 : 8.5	
Lactic acid	2.5	7.5 : 2.5	9.45	0.55 : 9.45	
Oxy-isobutyric acid	2.6	7.1 : 2.6	9.45	0.55 : 9.45	
Monochloric acid	7.0	3.0 : 7.0	9.8	0.2 : 9.8	
Trichloroacetic acid	9.9 : 10	0.1 : 9.9 : 10 : 0	10.0	
Methylsulphuric acid	9.2	0.8 : 9.2	9.6	0.4 : 9.6	

In the following table the relative affinities deduced from the above figures are given, compared with formic acid, as

well as with the numbers obtained by other methods taken from Ostwald's tables:—

Acids compared with Formic Acid.	Relative Affinities calculated from the Coefficient of Neutralisation for Red Lacmoid Paper.	Relative Affinities calculated from the Coefficient of Neutralisation for Blue Lacmoid Paper.	Calculated from Ostwald's Tables.		
			From the Rate of Decomposition of the Methyl Ether.	From the Electrical Conductivity.	From the Inversive Action on Cane Sugar.
Acetic acid	0.2592	0.267	0.2631	0.2523	0.2614
Propionic acid	0.2307	0.247	0.232	0.1934	..
Butyric acid	0.2028	0.238	0.229	0.1881	..
Isobutyric acid	0.1891	0.228	0.2045	0.1851	0.2189
Valerianic acid	0.2167	0.267	..	0.248	..
Lactic acid	0.777	0.808	0.687	0.619	0.6993
Oxy-isobutyric acid	0.8198	0.82	0.7022	0.738	0.6928

Experiments were also made with dibasic acids. The authors find that the affinity of one of the COOH groups for alkali is much larger when the other COOH is free than when it is already saturated. The difference is greatest in the case of strong acids.—H. T. P.

ORGANIC CHEMISTRY—QUANTITATIVE.

The Quantitative Estimation of Pentoses in Plants.

W. E. Stone. Ber. 1891, 24, 3019—3021.

In this process the material to be tested is as usual distilled with hydrochloric acid of 1.06 sp. gr. The distillate is neutralised with soda, then slightly acidified with acetic acid, and diluted to a known volume. The furfural in the liquid is estimated volumetrically by means of a solution of phenylhydrazine, containing 1 gm. of phenylhydrazine hydrochloride and 3 grms. of sodium acetate per 500 cc. This solution alters in strength rather quickly, and must, therefore, be frequently standardised on a solution of pure furfural (1 gm. pure furfural dissolved in a little acetic acid and diluted to 1,000 cc.). Titration is conducted as follows:—To 25 cc. of the distillate is added a known volume of phenylhydrazine solution. The mixture is rapidly boiled and cooled, and a small portion of the liquid (2 cc.) is filtered off perfectly bright from the precipitated hydrazone. The filtrate is mixed with twice its volume of Fehling's solution and boiled. In presence of the least excess of phenylhydrazine cuprous oxide is formed, and imparts to the liquid a characteristic greenish-yellow colour. When the furfural is in excess no reduction occurs. Another titration is then made with a fresh portion of distillate, more or less phenylhydrazine being employed, according to the indications of the previous experiment. 4—6 trials usually suffice to approximate within 0.1 cc. of the true volume of standard solution required. Below are given some results obtained by the above method:—

—H. T. P.

Determination of the Ash of Sugar. Alberti and Hempel. Zeits. f. angew. Chem. 1891, 486—492.

THE authors replace the sulphuric acid method by the following:—Six or 7 grms. of roughly powdered quartz sand are heated in a platinum dish and weighed. Five grms. of sugar are then added, the whole is thoroughly mixed and ignition is performed in a muffle. Two experiments are carried out at the same time as a check. For ashing the time varies from about half an hour to an hour and a quarter. In the case of molasses 3 grms. only are necessary, and ignition in the muffle is preceded by a preliminary warming. Copious tables of results are given.—T. L. B.

The Determination of Unsaponifiable Matter in Fats. M. Hönig and G. Spitz. Zeits. f. angew. Chem. 1891, 19, 565—568.

THE authors prefer the following process for the determination of unsaponifiable matter in fats:—7—10 grms. of fat are saponified with alcoholic potash, if necessary, under a vertical condenser, 30—40 cc. of water added, the mixture boiled up, cooled, transferred to a separating funnel, the flask rinsed with 50 per cent. alcohol, and then with 50 cc. of petroleum ether, which is added to the contents of the funnel. The petroleum separates rapidly from the alcoholic soap solution, and after the latter has been run off, is washed with 10—15 cc. of 50 per cent. alcohol two or three times. The treatment with petroleum ether is repeated to extract the remainder of the unsaponifiable matter; usually three extractions suffice. The evaporation of the solution in petroleum ether is facilitated by using a product obtained by fractionating the commercial article and collecting the portion distilling between 50° and 70° C. Should the unsaponifiable matter contain no light mineral oil the evaporation of the solvent may be quickened by heating more freely than is otherwise safe. With materials only saponified with difficulty it is advisable to repeat the saponification and subsequent operations. The advantage claimed for the new process over the usual method consists in the greater ease with which the separation of the petroleum ether is effected—a result due to the use of liquids containing a considerable proportion of alcohol.

When any determinations have to be made the following modification is of service:—The saponified solution, which should not measure more than 50 cc., is mixed with 20 cc. of petroleum ether and transferred to the extraction vessel A of the apparatus shown in the Figure, the flask being rinsed

APPARATUS FOR EXTRACTING SOAP SOLUTION.

with petroleum ether and 50 per cent. alcohol. At the bottom of A is a layer of small glass beads *g*, into which dips the end of the short thistle-headed funnel B. The surface of the soap solution is brought to about $\frac{1}{2}$ cm. of the opening of the discharge tube *h*. The small extraction flask E is attached by a cork to the lower part of the apparatus and about 20 cc. of the petroleum ether introduced through the funnel B; the upper part of the apparatus is connected with a reflux condenser in the ordinary way, and the operation is conducted as with a Soxhlet extractor, until the petroleum ether running back into the flask is quite colour-

less, and the soap solution in A has become clear. During the extraction the petroleum ether in flask E becomes turbid from the presence of a little soap, on which account it must, at the end of the extraction, be shaken out two or three times with 50 per cent. alcohol in a separating funnel.

A rapid method of determining unsaponifiable matter where only approximate results are required, consists in performing the saponification and extraction in a flask having a bulb of known capacity blown on its neck to contain the layer of petroleum ether from which an aliquot portion can be drawn by a pipette, and the fat determined by evaporating and weighing as usual. Experiments made on known mixtures show that the method is reliable.

The determination of water and dirt in oils such as are used in wool manufacture, with which the authors have been chiefly concerned, can be effected by dissolving 20 grms. of the well-mixed sample in about 100 cc. of petroleum ether, allowing the solution to remain at rest for an hour, and filtering through a weighed filter, taking care to allow no drops of water to pass on to the filter with the petroleum ether; after washing several times with petroleum ether, both the filter and the flask in which the fat was dissolved are freed from the solvent by cautious evaporation and weighed, the water being afterwards driven off and its amount and that of the dirt determined by re-weighing.

Another method consists in dissolving from 15–20 grms. in petroleum ether, pouring the solution into a burette previously filled to the lowest mark with water, reading off the amount of water in the sample when it has separated by standing, and determining the dirt by filtration through a weighed filter in the ordinary manner.—B. B.

The Calorific Value of the Constituents of Food and of their Derivatives. F. Stohmann and H. Langheim. J. Prakt. Chem. 1891, **44**, 336–339.

See under XVIII.—A., page 1020.

Percentage of Iodine absorbed by Lard Oil by the Hübl Method. R. Haines. Journ. Franklin Inst. 1891, **132**, 67–74.

Is a number of experiments on lard oil expressed by himself from pure lard, the author finds the average absorption of iodine in different samples to be 75.11 per cent., 53.13 per cent., and 70.01 per cent., respectively. Extra prime lard oil of Chicago manufacture guaranteed pure gave an average of 74.02 per cent.

To obtain trustworthy results the author finds it necessary to keep the burette containing the solution of iodine and mercuric chloride in alcohol at a constant temperature, and to protect it from draughts. For the solution of the oil only the purest chloroform should be used; the period of absorption is with advantage prolonged to eight hours, but should not under any circumstances exceed 24 hours. It is advisable to leave a large excess of unabsorbed iodine,

and for this purpose the liquid (after addition of a proportionately larger quantity of potassium iodide) should be diluted with 100 cc. of water, and not 150 cc. as prescribed by Hübl, as otherwise the quarter litre flasks are inconvenient to manipulate. Exactly the same quantities of chloroform and potassium iodide should be used in the oil tests and in the blank titration of the alcoholic iodine solution. The hyposulphite (thiosulphate) solution and the alcoholic iodine solution should be freshly prepared, the latter should be made up with very pure 95 per cent. alcohol.—S. B. A. A.

Analysis of Russian Waxes. J. Antousevich. J. Russ. Chem. Soc. 1891, **23**, 223–235.

See under XII., page 1014.

ANALYTICAL AND SCIENTIFIC NOTES.

Cobalt Dioxide. G. Vortmann. Ber. 1891, **24**, 2744–2749.

By the action of hypochlorites and hypobromites of the alkalis a blackish precipitate is obtained sensibly differing in character from ordinary cobalt hydrate, $\text{Co}_2(\text{OH})_6$. Carnot found such precipitate to be richer in oxygen than required by the sesquioxide formula (this Journal, 1889, 639). As this fact has an important bearing on the volumetric estimation of cobalt in presence of nickel, the author examined further into the question in the following manner:—Cobalt sulphate was gently warmed on the water-bath with decinormal iodine solution and caustic soda. An aliquot part after filtering was acidified with sulphuric acid, and the excess of iodine ascertained by the aid of thiosulphate solution: the results showed the relation of the number of cobalt atoms to the number of oxygen atoms to be 10 to 17, or in some cases 10 to 18; the relation 10 to 20 was never obtained. Oxidation with bromine water gave lower results—10 to 16. The high ratios obtained are considered to point certainly to the existence of the dioxide of cobalt. This dioxide is considered to be more unstable than the dioxide of manganese, which may be obtained by the same method.—T. L. B.

The Bismuth of Commerce and Purified Bismuth, together with some Remarks on the Atomic Weight of Bismuth. R. Schneider. J. Prakt. Chem. 1891, **44**, 23–48.

THE paper contains a detailed reply to the criticisms of Classen regarding the purity of the bismuth employed by the author in his determinations of the atomic weight of the metal. The author's result gave $\text{Bi} = 208$ ($\text{O} = 16$), whilst Classen finds $\text{Bi} = 208.89$ (Ber. 1890, **23**, 938). The following analyses of commercial bismuth and of pure bismuth obtained from various makers are given as proof of the utter fallacy of the statement that such products contain copper, iron and lead amounting to units per cent., as maintained by Classen:—

ANALYSES OF COMMERCIAL BISMUTH.

	99.963	99.989	99.989

An experimental result is also given to show that the bismuth obtained by precipitation as basic nitrate is free from all but traces of impurity. The analysis showed—

	Per Cent.
Bi.....	99.9893
Pb.....	0.0064
Cu.....	0.0043

The remainder of the paper is occupied with a discussion of the bearing of these results on the author's atomic weight determination (see following abstract).—C. A. K.

Reply (to R. Schneider's Paper on the Bismuth of Commerce, &c.) A. Classen. J. Prakt. Chem. 1891, **44**, 411—414. (Vide previous Abstract.)

THE author maintains his view that both the variation in the physical properties of bismuth generally sold as *puriss* as well as chemical analysis point to the impurity of the metal. In one case 500 grms. of the sample were found to yield 10 grms. of chloride of lead on analysis, and in another 1.56 per cent. of copper and 0.45 per cent. of iron were found in addition to the lead, which was not determined. The melting point of four samples were found to vary from 265°—273° C., whilst the metal obtained electrolytically by the method employed by the author in his atomic weight determination melts at 264° C.—C. A. K.

Di-ammonium Semi-Sulphate. (N_2H_4) H_2SO_4 . J. Curtius. J. Prakt. Chem. 1891, **44**, 101—102.

THE di-ammonium sulphate (N_2H_4) H_2SO_4 previously described by the author (J. prakt. Chem. **42**, 521), is not the neutral sulphate of hydrazine, as previously stated, but an acid sulphate. The neutral sulphate (N_2H_5) H_2SO_4 is obtained by neutralising sulphuric acid with hydrazine hydrate and then concentrating in a vacuum. It forms large, glittering, anisotropic plates which melt at 85° C. It is readily distinguished from the acid sulphate, which is only soluble with difficulty, by its being very hygroscopic and neutral. Alcohol precipitates the salt from aqueous solution in the form of an oil which is transformed into a crystalline powder on stirring with a glass rod, or on the addition of a crystal of the substance. —C. A. K.

New Book.

CHEMISCHE TECHNOLOGIE DER GESPINNSTEINFERN. Ihre Geschichte, Gewinnung, Verarbeitung und Veredlung. Von Dr. OTTO N. WITT, Professor der Technischen Chemie an der Königl. Tech. Hochschule zu Berlin. Zweite Lieferung. Braunschweig. Druck und Verlag von Friedrich Vieweg und Sohn, 1891. London: H. Grevel and Co., 33, King Street, Covent Garden.

THIS book is purely a continuation of the first part already noticed (this Journal, 1888, 872), containing no title-page, but commencing abruptly with the 193rd page and concluding with an unfinished sentence on page 384. It contains seven beautifully executed wood-engravings. The book begins with a continuation of a description of the drugs and chemicals used in the treatment of fibres in bleaching and purification. PART II. commences with Tannic Acid. It then proceeds to a new group, that of 3. The Alkalis, Alkaline Salts and Earths. This is followed by 4, Solvents, Purifying Agents and Grease Purifiers; and we then arrive at 5, Bleaching, Oxidising, and Reducing Agents. Next follow 6, Mordants, and first the Metallic or Inorganic Mordants and then the Mordants of Organic Origin. There are then a few words on Assistants such as Water-glass and Sodium Phosphate, as also Cows' dung. Section or Chapter 7* is devoted to Thickening Agents, Adhesive and Finishing Materials, and Part II. ends with an uncompleted treatise on 8. The Dye-stuffs. It seems clear from the commencement of this chapter that the author's intention is to give a very complete and clear account of the Dye-stuffs and Pigment-colours, more especially in their connection with the Dyer and Calico-printers' arts.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

RUSSIA.

Customs Decisions.

Note.—Pound = 36 lb. avoirdupois. Rouble = 3s. 2d.

The following decisions affecting the classification of articles in the Russian tariff have recently been given by the Russian Customs authorities:—

Carbon cylinders for dry element batteries prepared of coal, graphite, and pyrolusite, under section 71, point 4.—Duty, 4 roubles gold per pound.

Powdered glass, under section 71, point 5, letter *b*.—40 copecks gold per pound.

Graphite crucibles, under section 74, point 1.—Duty, 30 copecks gold per pound.

The Russian Department of Customs notifies that marble and cryolite ground to powder shall be admitted under section 66, point 5, of the Customs tariff.—Duty, 10 copecks gold per pound.

UNITED STATES.

Customs Decisions.

The following decisions respecting the construction to be given to Acts of Congress relating to the classification of articles in the Customs tariff, and the application of the Customs laws of the United States, have recently been given by the Customs authorities in that country:—

Memorandum tablets circular in shape, three inches in diameter, and consisting of three plain discs of collodion

protected by cardboard covers, each tablet being fastened by a single eyelet rivet, passing through one edge thereof, are dutiable at 60 cents per pound, and 25 per cent. *ad valorem*, under paragraph 21, N.T., as colloid or a compound of pyroxyline made into finished articles.

Liq. opir. sed. is dutiable at 40 per cent. under paragraph 47, N.T., as a liquid preparation of opium not specially provided for.

Bechirine sulphate, cocaine hydrochlorate, and hyoseamine sulphate are dutiable at 50 cents a pound as medicinal preparations in the preparation of which alcohol has been used.

Acetone is dutiable as a chemical compound at 25 per cent. under 76, N.T.

Dead oil produced by distillation from coal tar is dutiable at 25 per cent. *ad valorem*, under paragraph 76, Act of October 1st, 1890.

Photographic negatives are dutiable at 60 per cent.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

ARGENTINA.

Pharmaceutical Preparations.

The importation of medicinal and other drugs, perfumery, oils and varnishes has diminished largely, says the Austrian Consul, since the time when the Argentine Republic fell upon evil days financially. But at the same time there has been a constant increase in the importation of pitch, salt, stearin, bicarbonate of soda, and sulphuric acid. The production of the latter article, as well as of certain other heavy chemicals, has increased considerably in the Argentine Republic during the last few years.

ITALY.

Sulphur Mining in Sicily.

There has lately (says our Consul at Palermo, in Sicily) been a remarkable rise in the prices of sulphur in Sicily, due to several causes, among them the gradual exhaustion of the stocks at the outports, the closing of several mines, and the lessened production of last year. Unfortunately, this has so elated the owners of some of the mines that they have begun to extract more mineral than is required, and prices are already going down. The exportation of brimstone from Licata in 1890 remained 6,000 tons short of what it was in 1889, but its value amounted to 96,075*l.* more than in the previous year. The rise in the prices of this mineral during the second half of 1890 was as important as it proved to be unexpected and brisk, and it is due to the smaller production of last year, which is reckoned to have been 45,000 tons less than in 1889. Many mines in the Licata district which for some years were compelled to check their production, and even stop work, attracted by the fair prospects of the present high prices, have recommenced active work, and during the autumn of 1891 will throw a great quantity of sulphur on the market. In the Girgenti district many of the mines were flooded in the winter of 1890, owing to heavy rains, and could not work. Altogether the season was a favourable one to those engaged in the trade. Those working the mines are content if the prices remain at 3*s.* 9*d.* per cwt., and, when one compares the present cost of transport and of miners' wages with what they were twenty years ago, this price may be considered excellent.

RUSSIA.

The Duty on Chemicals.

Under the new Customs tariff the Russian duty on chemicals has been considerably increased; thus, caustic soda, hitherto 72 c. gold per pound, will now pay 90 c. gold; bleaching powder, from 52 c., is now dutiable at 70 c. gold;

borax, from 11 c. gold, has been raised to 120 c. per pound. Business in these particular goods is said to be at a standstill, the consumers not being able to pay the increased price. The rates under this head are, in fact, prohibitive, as they are intended to be, with a view to benefiting the native manufacturers. To what extent that object was already attained under the old, and (compared with the new) moderate tariff, appears from the following rates of dividend yielded by some of the leading Russian factories. The return is for 1889:—Russian Seed-crushing Company, 25 per cent.; Thornton's Woollen Manufactory, 40 per cent.; Neva Cotton Mill, 40 per cent.; Artificial Mineral-water Company, 82 per cent.; Russian-American India-rubber Company, clear profit on foundation capital, 86·4 per cent.

No industry has grown in larger proportion in Russia, under the protective system of the last decade, than that of chemicals and dyestuffs. A comparative table of the value of the produce of Russian industries, recently compiled, shows that while the total output of manufactures in the principal industries of the Empire has risen from 317 to 562 millions of roubles, or 77·4 per cent., between 1876 and 1888, that of chemicals and dyestuffs has advanced from 5·5 to 15·6 millions of roubles, or by 183·6 per cent.

GENERAL TRADE NOTES.

DIMINISHED PROFITS IN THE GERMAN CHEMICAL INDUSTRY.

Two of the principal chemical works in Germany have just issued reports of their commercial transactions during a portion of the year, which have created considerable astonishment in consequence of the great diminution in profits which they reveal. Schering's Chemische Fabrik in Berlin reports that, on the second of this month, a meeting of the board of directors took place, at which the report was read concerning the work during the first ten months of this year, based upon the results of the stock-taking on November 1st. It is stated that the strong competition which has been experienced during the present year has prevented the factory from selling its produce at higher prices, which would have counterbalanced the great expenditure for coal and for wages, amounting together to 106,125 m. in excess of the corresponding period of last year. Prices of chemicals generally, in fact, were somewhat below those of 1890. Another important item was that more money has been spent upon buildings and the renewal of plant, and that the general expenses have also been much higher, principally owing to the introduction of certain patented processes for chemical manufacture during the present year. The directors hope that in the future the profit for the manufacture of these patents will be considerable; but in the meantime the net profit for the ten months ending November 1st has been 542,543 m., or 328,142 m. less than in the same period of 1890. The net profit for the whole year 1889 was 814,451 m., in 1890 it was 925,400 m. Supposing the profits for the two closing months of this year to be in the same proportion to those in the ten months already past, the total profit for the year 1891 will not exceed 650,000 m. The great position which Schering's chemical factory occupies in German industry is shown by the accurate knowledge which the Stock Exchange has of the working of the factory. Long before the report above referred to was read at the meeting of the directors the shares of the factory commenced to fall very considerably on the Stock Exchange. The second unfavourable report emanates from the Actien Gesellschaft für Anilin Fabrikation, the directors of which report that the profits of their factory have been reduced in consequence of the increase in wages and in cost of crude material, which has not been balanced by higher rates for the finished products. A similar state of things prevailed in 1890. The dividends of the factory amounted in 1889 to 15 per cent., and in 1890 to 10 per cent.—*Chemist and Druggist.*

UNION OF GERMAN SOAP-MAKERS.

On December 6th a central association of German soap manufacturers was founded in Leipzig. The office of the Union is in Dresden, and its main objects are the promotion of the interests of the German soap-making industry, and the advancement of the technical education of those engaged in the business.—*Ibid.*

SALTS OF STRONTIUM IN WINE.

The Council of Hygiene for the department of the Seine has recommended the absolute prohibition of the use of salts of strontium in wine and treacle on account of their poisonous qualities. These salts are used by the wine growers of the South of France for removing plaster from wines. The process in use for the precipitation of sugar in treacle is also said to leave a considerable proportion of strontium in some treacles used for human food and for coffee-sweetening. The Council have deliberated upon the report of M. Riche on this subject, and have adopted his views, as above stated.—*Ibid.*

POST OFFICE NOTICE.

REDUCTION OF POSTAGE ON NEWSPAPERS, BOOKS, PATTERNS, &c., FOR PLACES ABROAD.

On and after January 1st, 1892, the postage chargeable on newspapers, books, printed papers, commercial papers, patterns, and samples for all destinations outside the United Kingdom, will be fixed uniformly at the undermentioned rates:—

For newspapers, books, and printed papers generally, $\frac{1}{2}$ d. per 2 oz.

For patterns and samples, $\frac{3}{4}$ d. per 2 oz., but with a minimum charge of 1d., as at present.

For commercial papers, $\frac{1}{2}$ d. per 2 oz., but with a minimum charge of 2 $\frac{1}{2}$ d.

The postage on packets containing more than one newspaper will no longer be chargeable on each paper, but simply according to the bulk weight of the packet.

The above-named rates should in all cases be prepaid: no pack can be sent forward wholly unpaid; but if by inadvertence the postage is insufficiently prepaid, double the deficit will be chargeable on delivery.

PAPERS OF INTEREST TO TECHNOLOGISTS AND MANUFACTURERS.

The following articles in the *Board of Trade Journal* for December will repay perusal:—

"The Tin-Plate Industry in the United States," p. 650.

"The Mining Industries of Mexico," p. 655.

"Industrial Openings in Bolivia," p. 661.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND
MACHINERY.

APPLICATIONS.

19,845. E. Brownhill. Improvements in taps for regulating the flow of gas. November 16.

19,983. J. K. Broadbent. Improvements in apparatus for regulating the supply of air to furnaces. Complete Specification. November 18.

20,049. H. J. White. Improvement in melting and heating furnaces. November 18.

20,065. T. Langer. Improvements in smokeless furnaces. Complete Specification. November 18.

20,118. A. S. Caldwell. Improvements in apparatus for evaporating and incinerating spent or used alkaline lyes or similar waste products. November 19.

20,123. T. Inman. An improved auger, manufactured of crucible cast steel for use in gas or chemical works. November 19.

20,125. G. Y. Blair. Improvements in apparatus for evaporating, condensing, and the like. November 19.

20,142. J. C. Mewburn.—From The Maschinenfabrik Grevenbroich, Germany. See Class XVI.

20,311. R. Cunliffe. Improvements in means for consuming smoke and destroying gases resulting from furnaces or gases from chemical operation. November 23.

20,413. G. Bamberg. See Class XI.

20,677. W. R. Jones. Improvements in furnaces. November 27.

20,736. R. Marshall and J. Westray. Improvements in furnaces. November 28.

20,788. E. Goedicke. Improvements in reverberatory furnaces. November 28.

20,852. P. L. Dermigny. An improved cooling and freezing apparatus. November 30.

20,904. C. H. Fitzmaurice. Improvements in apparatus and appliances for softening, purifying, and filtering liquids. December 1.

21,072. G. Johnston. Improvements in apparatus for drying moist substances or materials. December 3.

21,104. R. H. Leaker. See Class XVII.

21,157. J. Dawson. Improvements in thermometers. December 4.

21,248. W. Batlin. An improved tuyere. December 5.

21,307. J. A. Mays. A process and apparatus for centrifugally effecting the concentration or separation of solids. December 5.

21,459. C. C. Leathers. A new or improved evaporating apparatus. Filed December 8. Date applied for June 30, 1891, being date of application in France.

21,507. J. Brotherton. Improvements in bottles or holders for the storage and conveyance of quicksilver, gas, and other fluids under high pressure and in the method of manufacture thereof. December 9.

21,518. H. S. Elworthy. Improved cooling apparatus. Complete Specification. December 9.

21,548. T. Gaunt. Improvements relating to the evaporation and distillation of dry or liquid substances. December 9.

21,730. M. F. Purcell and G. Purcell. Improved apparatus for the purification of gaseous fumes, air, and the like, and the deposition of solid particles therefrom. December 11.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

957. H. Chilcott. Apparatus for intercepting and separating oleaginous and other matters from the water of condensation from surface condensers. November 25.

1385. A. Haigh and J. Thewlis. Apparatus employed in the drying of animal or vegetable fibres. December 16.

1540. W. H. Webb. Compression pumps for gaseous or vaporous fluids. December 2.

1579. L. H. Armour. See Class III.

2099. E. Blass. Apparatus for treating materials by a circulating current of heated gases. December 16.

2141. W. T. Cotton and E. L. Garrett. Improved evaporation and surface condenser for producing pure distilled water. December 9.

2142. W. T. Cotton and E. L. Garrett. Improved apparatus for distilling water and other liquids. December 9.

6798. A. J. Boulton.—From L. Falasconi, Italy. Kilns or furnaces. December 2.

18,216. S. Smithson. Apparatus for drying dyewoods, myrabolan grain, fuller's earth, night soil, and other pulpy matter. December 2.

18,483. T. Phipps. Stop valve for liquids, vapours, or gases. December 16.

18,901. E. Hesketh and O. J. Ellis. Improvement connected with the employment of carbonic acid gas in refrigerating apparatus. December 9.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

20,044. T. Littlehales. Improvement in the art or process of manufacturing heating and illuminating gases. November 18.

20,420. H. H. Lake.—From W. H. Harris, United States. Improvements relating to the manufacture of gas, and to apparatus therefor. November 24.

20,514. C. F. Claus and J. A. Elsner. Improvements relating to the production of oxygen, and to apparatus therefor. November 25.

20,573. J. Hargreaves. Improvements in feeding fuel to gas producers and in the generation of combustible gas. November 26.

20,780. A. Jabs. Improved method of manufacturing producer and water gas. November 28.

21,178. J. T. B. Bennett. Improved process of treating ashes or coal slack. December 4.

21,223. W. R. Alpe. The solidification of coal-dust or pit-slack. Complete Specification. December 5.

21,249. E. Drorg. Improvement in apparatus for charging inclined retorts for use in the manufacture of coal-gas, and for similar purposes. December 5.

21,337. S. J. Woodhouse. Improvements in or in connection with the furnaces of gas retorts. December 7.

21,481. O. G. Blunden. Improvements in apparatus for and the method of preparing peat or turf for use as fuel. December 8.

21,563. W. Bagley. Improved apparatus for feeding coal to gas producers. December 9.

21,598. V. B. Lewes. Improvements in the manufacture or production of carburetted hydrogen for illuminating purposes and apparatus therefor. December 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

19,504. F. J. Jones. Production of coke for foundry and other purposes. November 25.

1891.

1237. A. L. Keller. A new fuel. December 2.

1563. T. Clapham. Construction of condensers applicable for use in the manufacture of illuminating or other gases. December 9.

1909. J. W. Ormiston, A. R. Ormiston, and J. Ormiston. Manufacture and distribution of gaseous fuel, and arrangements and apparatus therefor. December 9.

2235. T. Williams. Combination or employment of ingredients for the manufacture of fire-lighters. December 9.

11,885. J. Bartlett. Fuel block and fire-lighter combined. December 2.

13,089. P. Dyorkovitz, The Kerosine Co., Ltd., and The Tank Storage and Carriage Co., Ltd. A new or improved method of and apparatus for distilling liquid hydrocarbons. December 16.

15,069. H. Fourness. Manufacture and storage of illuminating and heating gas. November 25.

17,222. W. Croswick. Improved arrangement of coke ovens and retorts for the manufacture of coke and illuminating gas. November 25.

17,652. H. H. Lake.—From The Thomson-Houston International Electric Co. Carbons for electric arc lamps. November 25.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATION.

20,753. E. H. Pickles and R. H. Pickles. Improvements in the purification of pyrolignites. November 28.

COMPLETE SPECIFICATION ACCEPTED.

1891.

1579. L. H. Armour. Improvements connected with ovens, furnaces, or retorts used for the making of coke or charcoal, or for distilling or roasting carbonaceous matter, or otherwise subjecting carbonaceous matter to the action of heat. November 25.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

19,062A. B. Willcox.—From the Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of colouring matters. Filed December 7. Date claimed under Rule XIX., November 4, 1891.

19,802. Read, Holliday, and Sons, Lim., and T. Holliday. Improvements in the manufacture of azo colouring matters. November 16.

19,847. O. Murray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of colouring matters from protocatechuic acid and phenols. November 16.

20,910. H. N. F. Schaeffer. Improvements in the manufacture of alizarin colours, and in the method of employing same in the process of dyeing. Complete Specification. November 18.

20,275. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in and relating to the manufacture and production of azo-dyes, and of materials therefor. November 21.

21,717. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of new derivatives of alizarin and its analogues. December 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

20,563. B. Willcox.—From the Farbenfabriken vormals F. Bayer and Co. Manufacture of indigo carmine from phenyl-glycocoll and its salts or ethers. December 2.

1891.

1351. O. Murray.—From the Farbwerke vormals Meister, Lucius, and Brüning. Production of a blue-green and red-violet colouring matter from alizarin blue. December 2.

2682. I. Levinstein. New or improved material for use in the production of colouring matters. December 2.

17,635. C. Dreyfus. Manufacture and production of colouring matters. November 25.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

20,149. H. H. Doty. Improvements relating to the waterproofing of canvas and other materials, and to compositions therefor. November 19.

20,610. E. Viarengo and E. Casper. Improvements in the treatment of rheu, and in apparatus therefor. November 26.

20,625. W. Bottomley.—From G. E. Armstrong, United States. Improvements in apparatus and processes for treating fibrous material. November 27.

COMPLETE SPECIFICATION ACCEPTED.

1891.

8644. C. Stephens. Improved means for damping, drying, dyeing, starching, or chemically treating and drying paper, silk, felts, and other like fabrics. December 9.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

20,010. H. N. F. Schaeffer. Improvements in the manufacture of alizarin colours, and in the method of employing same in the process of dyeing. Complete Specification. November 18.

20,103. P. G. Wild, G. Bentley, J. B. Jackson, and A. A. Whitley. A new or improved method of stamping and tinting textile fabrics and in apparatus for effecting same. November 19.

20,554. R. Hanson. Improvements in dyes or dyeing hat felts. November 26.

20,574. J. Longmore and R. Williamson. Improvements in or relating to the dyeing of silk and other fibres. November 26.

20,737. C. H. Nevill. An improved process for producing designs upon calico and other woven fabrics. November 28.

20,841. O. Imray.—From the Actien Gesellschaft fur Anilin Fabrikation, Germany. Process of dyeing cotton with nitroso compounds. November 30.

20,866. F. Hughes.—From A. Tiberghien, Belgium. Improvements in and in means for dyeing, mordanting, or bleaching textile fibres. Complete Specification. November 30.

20,899. W. Blackburn, R. E. Bray, and L. Clayton. Improvements in machinery for seouring and dyeing hanks of yarn. December 1.

20,931. L. Weldon. Improvements in yarn-dyeing machines. Complete Specification. December 1.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

478. H. A. Foster and J. Frost. Method of dyeing or colouring wool, silk, hair, fur, feathers, and other animal or vegetable fibres, or plain, cut pile, raised pile, or looped fabrics composed thereof. December 9.

41,692. J. Bertrand-Leplat. Apparatus for dyeing or bleaching textile materials. November 25.

17,887. F. Odenheimer. Process for printing and dyeing textiles, fibres, hair, feathers, and the like, by means of metal salts. November 25.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

20,037. C. Kellner. Improved process and apparatus for the manufacture or production of bleaching powder. November 18.

20,060. C. Kellner. Improved process and apparatus for the manufacture or production of hydrogen and chlorine from hydrochloric acid. November 18.

20,251. A. T. Hall and W. J. Wigg. See Class X.

20,636. C. Kilpatrick and The Ferrie Sewage and Water Purification Co. Means and apparatus for manufacturing ferrie chloride and other saturated solutions of oxides, metals, and the like. November 27.

20,713. C. Kellner. Improvements in the manufacture or production of chlorine and alkaline carbonates. November 27.

21,026. J. Raschen. Improvements in the manufacture of bicarbonate of soda. December 2.

21,130. A. Shearer. See Class XV.

21,328. J. Turner. The production and manufacture of certain cyanides, especially those of barium and potassium. December 7.

21,333. G. Dean and W. Ince. Chloride of lime by precipitation. December 7.

21,464. F. M. Lyte. Improvements in the production of chlorine, in the purification of certain base metals, in the recovery of precious or other metals with which the base metals may be associated, and in means or apparatus employed therein. December 8.

21,482. C. Simkin and C. G. Picking. Improvements in apparatus for concentrating sulphuric acid. December 9.

21,555. H. H. Lake.—From A. Raudnitz, Austria. Improvements relating to the manufacture of yellow prussiate of potash and to furnaces for use therein. December 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

20,012. F. Ellershausen. Treatment of soda waste. December 9.

1891.

962. J. W. Kynaston. Manufacture of sulphate of alumina. November 25.

1168. M. N. d'Andria. Manufacture of barium chloride and strontium chloride. December 2.

1261. O. Imray.—From La Société Anonyme des Anciennes Salines Domaniales de l'Est. Process for bleaching and purifying aluminium sulphate. December 2.

1824. I. Lifschutz. Process for the simultaneous production of cellulose and oxalic acid from vegetable fibrous substances. December 9.

2449. W. C. Heraens. Apparatus for concentrating acids. December 2.

17,933. W. P. Thompson.—From J. A. Bradburn and J. D. Pennoek. Manufacture of alumina. December 2.

18,324. L. Brunner and A. Zanner. Process for manufacturing nitrate of ammonia or chloride of ammonia, and simultaneously obtaining either precipitated phosphate of lime or an enriched phosphate of lime. December 2.

19,215. J. L. Kessler. Apparatus for the concentration of sulphuric acid. December 16.

19,382. C. Bigot and J. Schreiter. Manufacture of sodium borates. December 16.

19,453. A. J. Boulton.—From C. E. Ongley and O. D. Ballert. Preparation of salt. December 16.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

20,066. T. H. Sharpe. Improvements in the manufacture of articles moulded from clay or other plastic material, and in the apparatus employed therein. November 18.

20,096. J. P. Wilson. Improvements in kilns for drying and burning bricks and the like. November 19.

20,137. T. Walton. Improvements in the method of and apparatus for making blown glass ware. November 19.

20,200. W. H. Turner. Improvements in means employed for supporting plates and other articles in the glost oven and enamelling kiln. November 20.

20,280. Craven, Dunnill, and Co., Limited, and F. R. Smith. Improvements in the manufacture of tiles and the like, and in apparatus therefor. November 21.

20,415. L. West. Improvements in the manufacture of plate and other glass and apparatus therefor. November 24.

20,437. W. P. Thompson.—From R. S. Pease, United States. Improvements in the method of and apparatus for manufacturing plate glass. Complete Specification. November 24.

20,438. W. P. Thompson.—From R. S. Pease, United States. Improvements in the method of and apparatus for manufacturing glass plates, sheets, and films. Complete Specification. November 24.

20,439. W. P. Thompson.—From R. S. Pease. New or improved method of and apparatus for the manufacture of glass plates, cylinders, pipes, and certain other bodies. Complete Specification. November 24.

20,440. W. P. Thompson.—From R. S. Pease, United States. Improvements in the method of and apparatus for producing cylinders, pipes, and other tubular or hollow bodies of glass. Complete Specification. November 24.

20,523. F. Plant. Improvements in enamelling and hardening kilns for use in the manufacture of pottery. November 25.

20,641. H. Meller. Improvements in the application of photo-mechanical printing processes, for the decoration of every description of glass and pottery, and the production of photo-ceramic enamels, and the ornamenting of every description of enamel surface. November 27.

20,771. J. Slack. Improved means of producing decorative or other designs upon ceramic ware and the like. November 28.

20,861. J. E. G. Meran. A new product to serve as a substitute for pottery, for filtering purposes, and for the manufacture of tobacco pipes and the like. November 30.

21,350. F. Wetz. Process of making rose or orange-red stained glass. Complete Specification. December 7.

21,542. A. R. Carter and H. C. Hughes. Improvements in the manufacture of stained glass for windows and other transparencies and mural decoration. December 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

943. H. L. Doulton and S. H. Leech. Forming undercut projections and recesses in tiles and other articles of pottery and apparatus therefor. November 2.

7909. Craven, Dunnill & Co., Limited, and F. R. Smith. Manufacture of tiles, ceramic, mosaic, and the like, and in apparatus therefor. December 9.

14,381. C. Garcés-Losada. Baking ceramic plates and pottery. November 25.

18,189. L. Edwards.—From K. Goetz. Improvements in the liquid material or "slip" used in the manufacture of porcelain stone ware and the like. December 2.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

19,841. H. J. White. The improvement in manufacture of slag wool and cement. November 10.

20,096. J. P. Wilson. See Class VIII.

20,269. L. Haumann. Means for securing asphalt mastic as a coating or stopping upon all descriptions of buildings and building materials. November 24.

20,291. C. Doehrer. Improvements in the manufacture of corundum or alumina from emery. November 24.

20,646. H. Parry. Improvements in kilns for burning lime. November 27.

20,749. J. H. Blakesley. Improvements in fireproof floors, roofs, girders, joists, and the like. November 28.

20,743. J. T. Abell. Improvements in paving. November 28.

21,162. J. J. Carr. An improvement in or relating to the manufacture or treatment of whiting (carbonate of lime) and cements (sulphate of lime) and colours to be used for plastering or coating surfaces, also for modelling and moulding ornamental work. December 4.

21,199. R. Norwood. The manufacture of an improved compound for coating walls and other surfaces, and for the production of casts or mouldings, and for analogous purposes. December 4.

21,374. R. Norwood. The manufacture of an improved compound for coating walls and other surfaces, and for analogous purposes. December 7.

21,483. B. Peffard. Improvements in the manufacture of bricks to be used without mortar. December 9.

21,520. T. D. Harries. An improved artificial stone. December 9.

21,616. G. I. J. Wells. Improvements in the manufacture of cement, and the utilisation of the lime mud residue of the ammonia-soda process therefor. December 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,899. L. C. Delahaye. Improved method of enriching phosphated chalk and other calcareous phosphates. November 25.

1891.

1115. W. R. Taylor. Apparatus for the manufacture of cement. November 25.

1750. C. von Forell. Manufacture of artificial Roman cement. November 25.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

19,860. P. L. A. Montgolfier. Improvements relating to the manufacture of steel and other metal. Filed November 16. Date applied for June 11, 1891, being date of application in France.

19,928. A. Figge. Improvements in the manufacture of iron, steel, or copper, and a material to be used in the said manufacture. November 17.

19,992. S. Ward, W. Guest, and W. Miller. Improved manufacture of semi-divided bars of steel, and the like. November 18.

20,003. H. Y. Castner. Improvements in the manufacture of the oxides of the alkaline metals. November 18.

20,115. W. A. Briggs. An improved alloy for use in the manufacture of bicycles and tricycles. November 19.

20,131. C. T. J. Vautin. Improvements in the method of and apparatus for hardening, tempering, or annealing metallic wire or tape. November 19.

20,220. P. Williams. Improvements in the manufacture or purification of iron. November 20.

20,251. A. T. Hall and W. J. Wigg. Improvements in the utilisation of certain residuals obtained in the manufacture of copper. November 21.

20,461. E. K. Dutton.—From A. Mathies, Germany. Improvements in the production of hollow steel ingots, and in apparatus therefor. November 25.

20,856. O. Vogel. Improvements relating to the treatment of zinc and of alloys known as "hard spelter" or "hard zinc," produced in the coating of metal articles with zinc. November 30.

20,908. A. G. Meeze and R. Meikle. Manufacture of steel or homogeneous metal of higher grade from crude iron and the ores thereof. December 1.

20,977. J. R. Hunt. Improved method of reducing the bulk of scrap iron or other metals. Complete Specification. December 1.

21,114. E. Norton. Improvements relating to the coating of metals. December 3.

21,568. E. Hanff. Improvements in compound metal plates. December 9.

21,737. M. Lancon. New or improved manufacture of metallic alloys for soldering aluminium. December 11.

21,748. J. W. King, A. Colley, and J. Colley. Improvements in the removal of metals and metalloids previous to being charged into refining furnaces. December 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,830. J. T. King.—From T. S. Blair, jun. Reduction of ores. December 9.

18,898. T. D. Nicholls and The Cape Copper Company, Limited. Method of extracting copper from ores or compounds containing the same. November 25.

20,944. S. Elliott. Method of condensing lead and other metallic fumes arising from furnaces. December 2.

1891.

500. R. Heathfield. Process of coating metals. November 25.

1047. W. West. Apparatus and process for treating zinc ores. November 25.

1526. C. H. Aston. Method of utilising the calcined hot blast stove and boiler flue dust made in connexion with iron-making furnaces. December 16.

2000. P. Hart. Treatment of composite ores containing zinc. November 25.

4396. J. Strap. Separation of copper, nickel, and silver from mattes or alloys containing the same, and the treatment of the residues resulting therefrom. December 16.

7585. H. L. Herrenschmidt. Processes for the treatment of silicated nickel ores and pyritic ores of nickel and copper, or nickel, copper, and cobalt. December 2.

13,906. J. H. Darby. Basic-lined furnaces. December 9.

16,544. H. H. Lake.—From H. A. Harvey. Manufacture of armour plates. November 25.

17,933. W. P. Thompson.—From J. A. Bradburn and J. D. Pennock. See Class VII.

19,599. A. Fairley and J. P. Fairley. Manufacture of hollow ingots or other hollow castings from steel or ingot iron. December 16.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY

APPLICATIONS.

19,900. W. P. Thompson.—From C. L. Coffin, United States. Improvements in or relating to welding or working metals electrically. Complete Specification. November 17.

19,901. W. P. Thompson.—From C. L. Coffin, United States. Improvements in or relating to welding or working metals electrically. November 17.

20,312. J. M. Moffat. Improvement in the form of electrical battery cells, boxes, or vessels. November 23.

20,413. G. Bamberg. Improved electrolytic apparatus, more particularly applicable for manufacturing caustic soda and other products from salt, but also applicable to other purposes. November 24.

20,837. C. H. Woolf, A. E. Haymen, and A. D. R. Jameson. Extracting gold and silver from sea-water by electrolysis. November 30.

20,922. C. Lütke. Improvements in storage batteries or accumulators. December 1.

20,969. T. J. Holland. Improvements in electrolytic tanks. December 1.

21,442. H. H. Lake.—From I. L. Roberts, United States. Improvements in secondary or storage batteries. Complete Specification. December 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,523. H. Zerener. Apparatus for heating, welding, melting, or gasifying solid bodies by electricity. November 25.

1891.

49. W. Wensky. Galvanic batteries for producing constant currents. November 25.

899. H. T. Eager and R. P. Milburn. Electric cells or batteries. December 2.

1035. S. W. Marquay. Primary batteries. November 25.

3198. F. Poudronx. Galvanic batteries. November 25.

17,994. B. Scheithauer. Electric batteries. November 25.

18,431. M. Waddell, J. B. Entz, and W. A. Phillips. Secondary batteries. December 9.

18,522. W. P. Thompson.—From C. L. Coffin. Method and apparatus for welding or working metals electrically. December 2.

19,458. W. P. Thompson.—From N. H. Edgerton. Electric accumulators or storage batteries. December 16.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

20,415. H. E. Walter. An improved cleansing material. November 24.

20,512. R. R. Graf. A new or improved method of treating oils used for lubricating and tempering purposes to render the same incombustible or fireproof. Complete Specification. November 25.

20,590. E. J. T. Digby. Improvements in the manufacture of soap. November 26.

20,974. C. D. Abel.—From C. N. Scott and H. Hennebute, France. Improved method of, and apparatus for, purifying or treating soapy liquids for regaining therefrom soaps and fatty acids. December 1.

21,043. J. A. Wanklyn and W. Johnstone. Improvement in the manufacture of soap. December 2.

21,294. E. Simpson, C. H. Simpson, and H. McPhail. Improvements in the treatment of spent soap lyes for the purpose of obtaining glycerin and other products therefrom. December 5.

21,438. C. L. Field. An improved manufacture of superfatted soap. December 8.

COMPLETE SPECIFICATION ACCEPTED.

1891.

17,553. H. H. Lake.—From J. Ketchum. Lubricating compound for the chains and bearings of cycles and for other purposes. November 25.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

20,253. R. Ripley. Improvements in or appertaining to the form or get-up of bag-blue. November 21.

20,274. R. Lender. Improved rust and acid-proof paint. Complete Specification. November 21.

20,407. R. Pape. Improvements in the manufacture of a hard insulating material. Complete Specification. November 24.

21,203. J. C. Chapman.—From J. M. James, Japan. A process of and materials for coating metallic surfaces for the prevention of fouling and corrosion, and reducing surface friction. December 4.

21,241. G. H. Smith. Improvements in the treatment of gums for the preparation of varnishes therefrom. December 5.

21,279. W. J. Wigg. Improvements in the manufacture of Venetian red. Complete Specification. Filed December 5. Date applied for May 7, 1891, being date of application in United States.

21,545. E. Waller and C. A. Sniffen. Improvements in the manufacture of white lead and neutral lead acetate from lead ores. Complete Specification. December 9.

21,654. W. Morley. An anti-fouling composition for the bottoms of ships, yachts, and other vessels. December 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

13,861. A. A. Blandy. Combination and treatment of certain materials for the production of substances as a substitute for india-rubber and leather, and for other substances and purposes for which it may be applicable. December 9.

1891.

1267. W. N. Hartley and W. E. B. Blenkinsop. Manufacture of an improved preparation of driers or siccativ material for mixing with paints. November 25.

17,566. C. Dreyfus. Manufacture of coloured rubber goods or rubber-coated goods, and a material or preparation to be used in the said manufacture. December 9.

18,072. W. P. Thompson. From A. Freiherr (Baron) von Pereira. Manufacture or preparation of resinous paints. December 2.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

20,452. O. C. Hagemann. Improvements in the extraction and purification of tannin. November 24.

20,755. W. P. Thompson.—From F. Krauseder and A. Leutsch, Germany. Improvements in apparatus or appliances for use in drying sheets of glue, gelatin, and the like. November 28.

21,587. T. J. Haslam. An improved substitute for whalebone. December 10.

21,774. G. van Haeht and C. Obozinski. A new process for tanning, and apparatus relating thereto. December 12.

COMPLETE SPECIFICATION ACCEPTED.

1891.

1634. J. Sadler. Making an improved artificial leather. November 25.

XV.—AGRICULTURE AND MANURES.

APPLICATION.

21,130. A. Shearer. Improvements in the treatment of phosphates of alumina, or products containing such phosphates, to render them suitable for use as manures, or for the obtaining of soluble phosphates therefrom. December 3.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

20,119. J. Drummond. Improvements in apparatus for separating impurities from sugar. November 19.

20,142. J. C. Mewburn.—From The Maschinenfabrik Grevenbroich, Germany. Improvements in centrifugal machines or hydro-extractors for extracting sugar juice from crystals, and for other purposes. November 19.

20,887. D. Stewart. Improvements in evaporating or concentrating saccharine liquids, and in apparatus therefor. December 1.

21,059. C. Kleyer and C. Kappesser. See Class XIX.

21,370. L. Kern. Improvements in and relating to the production of adhesive substances soluble in water, from the gum exuded from almond, cherry, peach, and other trees. December 7.

21,477. W. P. Thompson.—From J. Hirsch, Germany. Improvements relating to the manufacture of cube, loaf, and similar sugar. December 8.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

19,849. P. A. Roche. Improvements relating to manufacture of beer. November 16.

19,986. W. S. Squire. Improvements in the manufacture of yeast. November 18.

20,556. W. P. Thompson.—From O. E. Nycander and G. Francke, Germany. Improved process for the production of yeast and spirit by the employment of ozonised air or oxygen. November 26.

20,649. C. Hof.—From Schneider, Germany. Improvements relating to the production of malt. Complete Specification. November 27.

20,733. G. Stadler. Improvements in barrels for sterilising beer. November 28.

21,059. C. Kleyer and C. Kappesser. See Class XIX.

21,104. R. H. Leaker. An improved method of and apparatus for condensing the vapour produced in brewers' coppers and like vessels, and for recovering the resultant liquid. December 3.

21,698. P. A. Attout, called Tailfer. Improvements in distilling, and in apparatus therefor. Filed December 11. Date applied for, May 16, 1891, being date of application in France.

21,708. S. Pitt.—From A. Savall, Sons and Co., France. Improvements in apparatus for distilling and rectifying. Complete Specification. December 11.

21,731. G. S. Kelsey. A new or improved instrument or apparatus for sampling or testing worts, and for other like purposes. December 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

852. F. König. Process and apparatus for the manufacture of champagne and other beverages charged with carbonic acid. November 11.

17,681. R. H. Leaker. An appliance for distributing and aerating brewers' wort. November 25.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

2444A. L. Smith. Improvements in means for storing and preserving food for domestic uses. Complete Specification. Filed November 28. Date claimed, February 10, 1891.

19,817. H. S. Elworthy. Improvements in means for preserving meat, fruits, and such like perishable articles in store or in transit. Complete Specification. November 16.

19,859. E. R. Kobert. An improved blood-forming substance and method of producing the same. November 16.

20,419. J. E. Alen. An improved method of preventing the curdling of albuminous solutions. Complete Specification. November 24.

20,436. W. P. Thompson. — From Moser and Co., Germany. Improvements in and connected with the process of extracting cocoa, or rendering it soluble for the preparation of soluble cocoa, or the manufacture of cocoa powder, chocolate, or the like preparations. Complete Specification. November 24.

20,602. J. Montgomerie. Improvements in and relating to the drying and roasting or treatment of celery and like vegetable matter, and appliances therefor. November 26.

20,694. B. Corrick. New or improved manufacture of substances or compositions for use as condiments. November 27.

21,317. J. Longshaw. Improvements in the method of and means for preserving eggs. December 7.

21,372. J. Carnrick. An improved process of manufacturing kumyss compounds or kumyss tablets. Complete Specification. December 7.

21,391. D. Evans. — From A. A. Freeman and G. Evans, United States. An improvement in the method or process of preserving oysters and other bivalves in the shell. December 8.

21,708. S. Pitt. — From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Process for preserving organic substances, and for disinfection. December 11.

B.—Sanitary Chemistry.

19,803. H. P. Boulnois and J. A. Brodie. Improvements in and relating to refuse destructors. November 16.

20,682. J. Price. Improvements in the treatment of sewage. November 27.

20,726. J. Norris. Improvements in the disposal of sewage and apparatus connected therewith. Complete Specification. November 28.

20,748. F. Scudder. Treatment of and production of valuable products from sludge obtained by electrical treatment of sewage. November 28.

21,029. P. Hart. Improvements in treatment of sewage, faecal, and other like matters by means of galvanised waste iron chloride liquors. December 2.

21,090. H. Lockwood. Improvements in the materials used in the purification of sewage and other foul water. December 3.

21,292. F. P. Candy. See Class XVIII.—C.

C.—Disinfectants.

20,395. A. Robertson. The Highland sheep dip. November 24.

21,292. F. P. Candy. Improvements in the manufacture of materials for the treatment of sewage and other polluted waters. December 5.

21,706. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. See Class XVIII.—A.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

2207. M. P. Hatschek, G. A. Clowes, and L. Briant. Preparation of peptone extracts, and application of the same to various useful purposes. December 9.

3481. J. Billaby. A preparation of extract of malt in combination with extract of liquorice and other substances. November 25.

17,717. B. J. B. Mills. — From A. M. de la Visuville. Process for preserving eggs. November 25.

17,899. J. Kay. Method of preserving fruit. December 2.

18,615. J. Quaglio. Process for roasting pure coffee and for condensing the steam produced during the roasting operation in coffee substitutes or in sugar for the purpose of the extracting the aroma and products therefrom. December 9.

B.—Sanitary Chemistry.

1890.

15,405. J. Hardwick and L. A. Newton. The treating of sewage and sewage sludge. December 2.

1891.

1225. H. Tatham. Treatment of sewage and sewage deposits. December 2.

5330. E. E. Scruby. Process for purifying sewage effluents and other impure liquids, and apparatus therefor. December 16.

C.—Disinfectants.

1891.

8629. W. H. Spencer. Apparatus for vaporising oils and other liquids for medicinal and disinfecting purposes. December 2.

18,434. S. B. Mores and T. F. Bourne. Sulphur candles. December 2.

18,913. A. Lembach, U. Schleicher, and C. J. Wolff. Improvements in and relating to soluble quinoline antiseptics. December 9.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

20,163. A. Watkins. See Class XXI.

20,224. T. Lumb. Improvements in machinery or apparatus for the manufacture of press papers, glazed boards, and the like. November 20.

20,225. C. Kellner. Improvements in the treatment of short fibres, particularly paper pulp, forming therefrom rovings and other goods. November 20.

21,059. C. Kleyer and C. Kappesser. Improvements in the treatment of peat for the production of cellulose, sugar, and alcohol. Complete Specification. December 2.

21,340. J. Longshaw. Improvements in the treatment of strawboards and millboards. December 7.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

927. R. N. Redmayne. Manufacture of pulp for paper-making and other purposes. November 25.

2872. J. Beveridge. Treatment of fibrous plants for the manufacture of paper pulp. November 25.

15,222. C. W. Robinson. Machine for making parchmentised fibre and the like. November 25.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

20,851. R. A. Cheesbrough. Improvements in the manufacture of perfumes. November 30.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

21,044. A. Fockling. Process for the preparation of hop extract. November 25.

1891.

588. H. H. Lake.—From Ichthyolgesellschaft Cordes, Hermann and Co. Coatings for therapeutical purposes. November 25.

17,493. A. Bang.—From G. A. Dahl. New anti-pyretic and anti-neuralgie chinidin derivative (to be called "Analgen-Du Vis") and process for the production of the same. November 25.

17,654. C. D. Hellstrom. Method and apparatus for extracting fatty particles from emulsions. November 25.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

20,068. H. M. Campbell. Improvements in and connected with photographic sensitised plates. November 18.

20,163. A. Watkins. Improvements in sensitive papers for actinometers. November 20.

20,557. T. H. Powell. An improvement in the method of, and materials or compound employed, in toning photographic prints on paper, glass, or other surfaces. November 26.

20,600. R. Kopp. Improvements relating to photography in natural colours. Complete Specification. November 26.

20,690. J. Hauff. The use of aromatic amido compounds, and of derivatives of pyrogallol for the development of photographic images. November 27.

21,381. J. T. Sandell. An improvement in the manufacture of photographic plates and films or other sensitive media. December 7.

21,497. J. J. E. Mayall. Improvements connected with colouring photographic impressions, and in the mixing and preparing of the colours used therewith. December 9.

COMPLETE SPECIFICATION ACCEPTED.

1891.

18,592. E. Hackh. Photographic apparatus. December 9.

XXII.—EXPLOSIVES, MATCHES, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

336. Y. Y. Johnson.—From Zellstoff fabrik Walldhof. Treatment of cellulose nitrates or gun-cotton. November 25.

843. G. G. André and C. H. Curtis. Manufacture of gunpowder, and in apparatus therefor. November 25.

2,044. N. Erbsloh. New or improved fuse for igniting the explosive charges of shells and other projectiles. December 9.

11,713. M. Renland. Manufacture of explosives. December 9.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATIONS.

20,339. H. S. Kenting. Apparatus for determining specific gravities of liquids. November 23.

20,632. W. I. Chadwick. Improvements in condensers used in instruments for optical projection. November 27.

20,956. W. Johnstone. Improvements in detection of foreign fats in butter. December 1.
